

QUADRATIC RESIDUE PATTERNS MODULO A PRIME

KEITH CONRAD

1. INTRODUCTION

Let p be an odd prime. Among the nonzero numbers in \mathbf{F}_p , half are squares and half are nonsquares. The former are called quadratic residues and the latter are called quadratic nonresidues. We do not consider 0 to be a quadratic residue or nonresidue, even though it is of course a square.

If a is a quadratic residue in \mathbf{F}_p^\times , is $a + 1$ more or less likely to be a quadratic residue? If a is a quadratic nonresidue in \mathbf{F}_p^\times , is $a + 1$ more or less likely to be a quadratic nonresidue? Let's look at some data.

Example 1.1. Taking $p = 19$, the 9 quadratic residues are 1, 4, 5, 6, 7, 9, 11, 16, 17, and the 9 quadratic nonresidues are 2, 3, 8, 10, 12, 13, 14, 15, 18. In the table below we indicate when a and $a + 1$ are quadratic residues (QR) for $a \in \mathbf{F}_{19}^\times$.

a	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
a is QR?	✓			✓	✓	✓	✓		✓		✓					✓	✓	
$a + 1$ is QR?			✓	✓	✓	✓		✓		✓					✓	✓		

There are 17 pairs $(a, a + 1)$ where a and $a + 1$ are nonzero in \mathbf{F}_{19} (all a aside from 0 and 18). The table above tells us that 4 pairs have a and $a + 1$ as quadratic residues ($a = 4, 5, 6, 16$), 5 pairs have a as a quadratic residue and $a + 1$ as a quadratic nonresidue ($a = 1, 7, 9, 11, 17$), 4 pairs have a as a quadratic nonresidue and $a + 1$ as a quadratic residue ($a = 3, 8, 10, 15$), and 4 pairs have a and $a + 1$ as quadratic nonresidues ($a = 2, 12, 13, 14$, noting 18 doesn't count since $18 + 1 = 0$). The four options for a and $a + 1$ to be quadratic residues or nonresidues are approximately equally likely (around 25% each).

Example 1.2. When $p = 101$, there are 99 pairs $(a, a + 1)$ where a and $a + 1$ are nonzero in \mathbf{F}_{101} (all $a \neq 0, 100$). Among these pairs, a and $a + 1$ are quadratic residues 24 times, a is a quadratic residue and $a + 1$ is a quadratic nonresidue 25 times, a is a quadratic nonresidue and $a + 1$ is a quadratic residue 25 times, and a and $a + 1$ are quadratic nonresidues 25 times. These counts are equal or nearly equal.

There are 98 triples $(a, a + 1, a + 2)$ where $a, a + 1$, and $a + 2$ are nonzero in \mathbf{F}_{101}^\times : all a aside from 0, 99, and 100. Using $+$ to denote a quadratic residue and $-$ to denote a quadratic nonresidue, the following table says the frequency of the quadratic residue patterns among the triples $(a, a + 1, a + 2)$ in \mathbf{F}_{101}^\times is nearly uniform.

$(a, a + 1, a + 2)$	(+, +, +)	(+, +, -)	(+, -, +)	(-, +, +)
Count	12	12	12	12
$(a, a + 1, a + 2)$	(+, -, -)	(-, +, -)	(-, -, +)	(-, -, -)
Count	13	12	13	12

Example 1.3. The tables below count how many pairs $(a, a + 1)$ and triples $(a, a + 1, a + 2)$ in \mathbf{F}_{1009}^\times have different quadratic residue patterns. The counts look nearly uniform in each case.

$(a, a + 1)$	(+, +)	(+, -)	(-, +)	(-, -)
Count	251	252	252	252
$(a, a + 1, a + 2)$	(+, +, +)	(+, +, -)	(+, -, +)	(-, +, +)
Count	128	122	122	122
$(a, a + 1, a + 2)$	(+, -, -)	(-, +, -)	(-, -, +)	(-, -, -)
Count	130	130	130	122

These examples suggest that the possible quadratic residue patterns of a fixed length in \mathbf{F}_p^\times are approximately equally likely. For a set of r consecutive numbers in \mathbf{F}_p^\times , allowing for 2^r choices of their quadratic residue or nonresidue status, we will show the frequency of each quadratic residue pattern is nearly $p/2^r$, which is what we'd expect if we were discussing r independent random variables on \mathbf{F}_p that each have two outcomes.

2. THE MAIN THEOREM

For $r \geq 1$ and an odd prime $p > r$, we want to count how many r -tuples of consecutive numbers $a, a + 1, \dots, a + r - 1$ in \mathbf{F}_p^\times have predetermined quadratic residue or nonresidue behavior. (We need $p > r$ so that \mathbf{F}_p^\times contains at least r elements.) We will use the Legendre symbol. For a choice of r signs $\varepsilon_1, \dots, \varepsilon_r \in \{\pm 1\}$, set

$$\begin{aligned} N_p(\varepsilon_1, \dots, \varepsilon_r) &= \left| \left\{ a \in \mathbf{F}_p^\times : \left(\frac{a}{p} \right) = \varepsilon_1, \left(\frac{a+1}{p} \right) = \varepsilon_2, \dots, \left(\frac{a+r-1}{p} \right) = \varepsilon_r \right\} \right| \\ &= \left| \left\{ a \in \mathbf{F}_p^\times : \left(\frac{a+i-1}{p} \right) = \varepsilon_i \text{ for } i = 1, \dots, r \right\} \right|. \end{aligned}$$

In the tables in Examples 1.2 and 1.3, the + corresponds to Legendre symbol 1 and the - corresponds to Legendre symbol -1. For instance, Example 1.2 tells us that $N_{101}(1, 1, 1) = 12$ and $N_{101}(1, -1, -1) = 13$. Here is the main result.

Theorem 2.1. *For r signs $\varepsilon_1, \dots, \varepsilon_r \in \{\pm 1\}$ and an odd prime $p > r$, $N_p(\varepsilon_1, \dots, \varepsilon_r) = p/2^r + O_r(\sqrt{p})$. More precisely,*

$$\left| N_p(\varepsilon_1, \dots, \varepsilon_r) - \frac{p}{2^r} \right| < (r-1)\sqrt{p} + \frac{r}{2}.$$

Proof. We will write down a formula for $N_p(\varepsilon_1, \dots, \varepsilon_r)$ in terms of a sum of Legendre symbol products, extract the main term $p/2^r$, and bound what is left.

We begin with a counting formula. For $b \in \mathbf{F}_p^\times$ and $\varepsilon = \pm 1$,

$$1 + \varepsilon \left(\frac{b}{p} \right) = \begin{cases} 2, & \text{if } \left(\frac{b}{p} \right) = \varepsilon, \\ 0, & \text{if } \left(\frac{b}{p} \right) \neq \varepsilon, \end{cases}$$

so

$$(2.1) \quad \frac{1}{2} \left(1 + \varepsilon \left(\frac{b}{p} \right) \right) = \begin{cases} 1, & \text{if } \left(\frac{b}{p} \right) = \varepsilon, \\ 0, & \text{if } \left(\frac{b}{p} \right) \neq \varepsilon. \end{cases}$$

Therefore if $b_1, \dots, b_r \in \mathbf{F}_p^\times$ and $\varepsilon_1, \dots, \varepsilon_r \in \mathbf{F}_p^\times$,

$$\prod_{i=1}^r \frac{1}{2} \left(1 + \varepsilon_i \left(\frac{b_i}{p} \right) \right) = \begin{cases} 1, & \text{if } \left(\frac{b_i}{p} \right) = \varepsilon_i \text{ for all } i \in \{1, \dots, r\}, \\ 0, & \text{if } \left(\frac{b_i}{p} \right) \neq \varepsilon_i \text{ for some } i \in \{1, \dots, r\}, \end{cases}$$

so

$$\begin{aligned} N_p(\varepsilon_1, \dots, \varepsilon_r) &= \left| \left\{ a \in \mathbf{F}_p^\times : \left(\frac{a+i-1}{p} \right) = \varepsilon_i \text{ for } i = 1, \dots, r \right\} \right| \\ &= \sum_{\substack{a \in \mathbf{F}_p \\ a, a+1, \dots, a+r-1 \neq 0}} \prod_{i=1}^r \frac{1}{2} \left(1 + \varepsilon_i \left(\frac{a+i-1}{p} \right) \right). \end{aligned}$$

What can we say about missing terms in the outer sum, where $a+j-1 = 0$ in \mathbf{F}_p for some $j \in \{1, \dots, r\}$? Then $\frac{1}{2} \left(1 + \varepsilon_j \left(\frac{a+j-1}{p} \right) \right) = \frac{1}{2}$ while $\frac{1}{2} \left(1 + \varepsilon_i \left(\frac{a+i-1}{p} \right) \right)$ is 0 or 1 for $i \neq j$, so

$$\left| \prod_{i=1}^r \frac{1}{2} \left(1 + \varepsilon_i \left(\frac{a+i-1}{p} \right) \right) \right| \leq \frac{1}{2}.$$

There are r such terms (corresponding to $a = 0, a = -1, \dots, a = -(r-1)$ in \mathbf{F}_p), so

$$\begin{aligned} N_p(\varepsilon_1, \dots, \varepsilon_r) &= \sum_{a \in \mathbf{F}_p} \prod_{i=1}^r \frac{1}{2} \left(1 + \varepsilon_i \left(\frac{a+i-1}{p} \right) \right) + \frac{e_r}{2}, \quad \text{where } |e_r| \leq r, \\ &= \frac{1}{2^r} \sum_{a \in \mathbf{F}_p} \prod_{i=1}^r \left(1 + \varepsilon_i \left(\frac{a+i-1}{p} \right) \right) + \frac{e_r}{2}. \end{aligned}$$

Let's expand the product inside the sum: for each $a \in \mathbf{F}_p$,

$$\begin{aligned} \prod_{i=1}^r \left(1 + \varepsilon_i \left(\frac{a+i-1}{p} \right) \right) &= 1 + \sum_{\substack{S \subset \{1, \dots, r\} \\ S \neq \emptyset}} \left(\prod_{i \in S} \varepsilon_i \left(\frac{a+i-1}{p} \right) \right) \\ &= 1 + \sum_{\substack{S \subset \{1, \dots, r\} \\ S \neq \emptyset}} \left(\prod_{i \in S} \varepsilon_i \right) \left(\frac{f_S(a)}{p} \right), \end{aligned}$$

where $f_S(x) = \prod_{i \in S} (x+i-1)$. The polynomial $f_S(x) \in \mathbf{F}_p[x]$ is separable with degree $|S|$. Feeding the above expression for the product into the formula for $N_p(\varepsilon_1, \dots, \varepsilon_r)$ and swapping the order of summation,

$$\begin{aligned} N_p(\varepsilon_1, \dots, \varepsilon_r) &= \frac{1}{2^r} \sum_{a \in \mathbf{F}_p} \left(1 + \sum_{\substack{S \subset \{1, \dots, r\} \\ S \neq \emptyset}} \left(\prod_{i \in S} \varepsilon_i \right) \left(\frac{f_S(a)}{p} \right) \right) + \frac{e_r}{2} \\ &= \frac{p}{2^r} + \frac{1}{2^r} \sum_{\substack{S \subset \{1, \dots, r\} \\ S \neq \emptyset}} \left(\prod_{i \in S} \varepsilon_i \right) \sum_{a \in \mathbf{F}_p} \left(\frac{f_S(a)}{p} \right) + \frac{e_r}{2}. \end{aligned}$$

We have found the desired term $p/2^r$ in the formula for $N_p(\varepsilon_1, \dots, \varepsilon_r)$ and want to show the rest of the formula is small.¹

¹This technique of relating $N_p(\varepsilon_1, \dots, \varepsilon_r)$ to $p/2^r$ goes back at least to Jacobsthal in 1906 when $r = 2$ [6, p. 27]. For a more recent account of it, see replies to the MathOverflow post ‘‘Consecutive non-quadratic residues’’ at <https://mathoverflow.net/questions/161271/consecutive-non-quadratic-residues>.

The product $\prod_{i \in S} \varepsilon_i$ is ± 1 , so by the triangle inequality

$$(2.2) \quad \left| N_p(\varepsilon_1, \dots, \varepsilon_r) - \frac{p}{2^r} \right| \leq \frac{1}{2^r} \sum_{\substack{S \subset \{1, \dots, r\} \\ S \neq \emptyset}} \left| \sum_{a \in \mathbf{F}_p} \left(\frac{f_S(a)}{p} \right) \right| + \frac{r}{2}.$$

The inner sum over \mathbf{F}_p on the right side can be estimated with *Weil's bound*, which says in a special case that for nonconstant $f(x) \in \mathbf{F}_p[x]$ having no repeated roots (that is, are separable),

$$(2.3) \quad \left| \sum_{a \in \mathbf{F}_p} \left(\frac{f(a)}{p} \right) \right| \leq (\deg f - 1)\sqrt{p}.$$

(This inequality is an equality if $\deg f = 1$, and generally is a strict inequality if $\deg f \geq 2$.) Applying (2.3) to the polynomials $f_S(x)$, which each have no repeated roots, we get

$$\left| \sum_{a \in \mathbf{F}_p} \left(\frac{f_S(a)}{p} \right) \right| \leq (\deg f_S - 1)\sqrt{p} = (|S| - 1)\sqrt{p} \leq (r - 1)\sqrt{p}.$$

This upper bound is independent of S , so feeding it into (2.2) gives us

$$\begin{aligned} \left| N_p(\varepsilon_1, \dots, \varepsilon_r) - \frac{p}{2^r} \right| &\leq \frac{1}{2^r} \sum_{\substack{S \subset \{1, \dots, r\} \\ S \neq \emptyset}} ((r - 1)\sqrt{p}) + \frac{r}{2} \\ &= \frac{1}{2^r} (2^r - 1)(r - 1)\sqrt{p} + \frac{r}{2} \\ &< (r - 1)\sqrt{p} + \frac{r}{2}. \end{aligned}$$

□

For each r , the count $N_p(\varepsilon_1, \dots, \varepsilon_r) = p/2^r + O_r(\sqrt{p})$ tends to ∞ as $p \rightarrow \infty$, so in particular $N_p(\varepsilon_1, \dots, \varepsilon_r) \geq 1$ for all large p . We can determine the largest prime modulo which there are *not* r consecutive quadratic residues mod p by setting $N_p(1, 1, \dots, 1) = 0$ in Theorem 2.1 to get an upper bound on the possible p .

Example 2.2. What is the largest prime p for which there are not 3 consecutive quadratic residues mod p ? This is asking when $N_p(1, 1, 1) = 0$. The bound in Theorem 2.1 implies $p/8 < 2\sqrt{p} + 3/2$, so $p < 16\sqrt{p} + 12$. That implies $p < 279.4$, so $p \leq 277$. Checking all primes up to 277, the last one without 3 consecutive quadratic residues is $p = 17$.

That there are three consecutive quadratic residues modulo p for $p \geq 19$ is due to Jacobsthal [6, p. 30].

The proof of Theorem 2.1 can be used to count quadratic residue patterns with gaps that are not necessarily consecutive: if $p > r$ and c_1, \dots, c_r are distinct in \mathbf{F}_p , the set

$$\left\{ a \in \mathbf{F}_p^\times : \left(\frac{a + c_i}{p} \right) = \varepsilon_i \text{ for } i = 1, \dots, r \right\}$$

for each choice of signs $\varepsilon_1, \dots, \varepsilon_r \in \{\pm 1\}$ has a size N_p , say, that satisfies the same estimate as in Theorem 2.1:

$$\left| N_p - \frac{p}{2^r} \right| < (r - 1)\sqrt{p} + \frac{r}{2}.$$

The only change needed in the proof of Theorem 2.1 is to replace the polynomial $f_S(x) = \prod_{i \in S} (x + i - 1)$ with $\prod_{i \in S} (x + c_i)$.

The Weil bound (2.3) extends to all finite fields, not just those of odd prime order p , with the Legendre symbol on \mathbf{F}_p replaced by a nontrivial multiplicative character on \mathbf{F}_q and \sqrt{p} in the Weil bound replaced by \sqrt{q} . In particular, for an odd prime power q , if χ is the quadratic character on \mathbf{F}_q^\times then for distinct c_1, \dots, c_r in \mathbf{F}_q and any signs $\varepsilon_1, \dots, \varepsilon_r \in \{\pm 1\}$,

$$N_q := \left| \left\{ a \in \mathbf{F}_q^\times : \chi(a + c_i) = \varepsilon_i \text{ for } i = 1, \dots, r \right\} \right|$$

satisfies

$$\left| N_q - \frac{q}{2^r} \right| < (r - 1)\sqrt{q} + \frac{r}{2}.$$

3. SOME HISTORY

The first work on counting quadratic residue patterns of two or more consecutive terms in \mathbf{F}_p^\times was by Aladov [1] in 1896. He counted each quadratic residue pattern of length 2 and, for $p \equiv 3 \pmod{4}$, the number of consecutive triples of quadratic residues (not general patterns of length 3). The counts of length 2 imply $N_p(\varepsilon_1, \varepsilon_2) = p/4 + O(1)$. In 1898, Sterneck [8] counted patterns of length 3 and 4 with restrictions (each pattern was counted together with its opposite, *e.g.*, $(+, +, -)$ and $(-, -, +)$ together, not separate). In 1906, Jacobsthal [6, Chap. III] in his dissertation found exact formulas for the number of quadratic residue patterns of length 2 and 3 in \mathbf{F}_p^\times . The length 3 counts imply $N_p(\varepsilon_1, \varepsilon_2, \varepsilon_3) = p/8 + O(\sqrt{p})$.

Davenport considered this counting problem for $r \geq 4$ throughout the 1930s. In [2] he bounded the error $|N_p(\varepsilon_1, \dots, \varepsilon_r) - p/2^r|$ as $O_r(p^{3/4})$ for $r = 4$ and 5 by *ad hoc* methods that did not extend easily to $r \geq 6$. In [3] he used other tricks for $6 \leq r \leq 9$ that led to error bounds $O_r(p^{7/8})$ for $r = 6$ and 7, and $O_r(p^{19/20})$ for $r = 8$ and 9, and he could reduce the error bound when $r = 4$ from $O_r(p^{3/4})$ to $O_r(p^{2/3})$. Reducing the exponent on p in the error bound is closely related to bounding the real parts of the zeros of the zeta-function of curves $y^2 = f(x)$ over \mathbf{F}_p . Davenport continued to refine his techniques throughout the 1930s, and in [4, Theorem 5] he got an error bound of the form $O_r(p^{1-\theta_r})$ for general r with an explicit formula for θ_r that tends to 0 as $r \rightarrow \infty$. A definitive error bound $O_r(\sqrt{p})$ for all r , coming from the bound in (2.3), was given by Weil [9] (see also [5, Theorem 3.1]) after he proved the Riemann hypothesis for curves over finite fields.

An account of the work by Davenport, along with how it influenced Hasse and Mordell, is in [7, Sect. 3].

APPENDIX A. EXTENDING THEOREM 2.1 BEYOND THE LEGENDRE SYMBOL

The Weil bound (2.3) for the Legendre symbol on \mathbf{F}_p has a generalization to other multiplicative characters on finite fields: if χ is a nontrivial multiplicative character on \mathbf{F}_q with order $n \geq 2$ and $f(x) \in \mathbf{F}_q[x]$ is monic and not an n -th power, then

$$(A.1) \quad \left| \sum_{a \in \mathbf{F}_q} \chi(f(a)) \right| \leq (r - 1)\sqrt{q}.$$

where $f(x)$ has r distinct roots in a splitting field over \mathbf{F}_q . This is [5, Theorem 3.1]².

²In [5] it is assumed for (A.1) that $f(x)$ is not an n -th power but it is not explicitly stated that $f(x)$ is not monic too. For non-monic f we get counterexamples to (A.1): if $f(x) = cg(x)^n$ with $c \in \mathbf{F}_q^\times$ not an n -th power, then $\sum_{a \in \mathbf{F}_q} \chi(f(a)) = \sum_{a \in \mathbf{F}_q} \chi(cg(a)^n) = \chi(c)(q - \{a \in \mathbf{F}_q : g(a) \neq 0\})$, so $|\sum_{a \in \mathbf{F}_q} \chi(f(a))| =$

Using (A.1) we will prove the following generalization of Theorem 2.1.

Theorem A.1. *Let χ_1, \dots, χ_r be nontrivial multiplicative characters on \mathbf{F}_q , where χ_i has order $n_i \geq 2$. For $r < q$, pick distinct c_1, \dots, c_r in \mathbf{F}_q and an n_i -th root of unity ε_i in \mathbf{C} for $i = 1, \dots, r$. Set*

$$N_q = |\{a \in \mathbf{F}_q : \chi_i(a + c_i) = \varepsilon_i \text{ for } i = 1, \dots, r\}|.$$

Then

$$\left| N_q - \frac{q}{n_1 \dots n_r} \right| < (r-1)\sqrt{q} + \frac{r}{2}.$$

When $q = p$ and all χ_i are quadratic ($n_i = 2$ for all i), Theorem A.1 becomes Theorem 2.1.

We take $r < q$ in Theorem A.1 because if $r \geq q$ then for each $a \in \mathbf{F}_q$ the numbers $a + c_1, \dots, a + c_r$ fill up \mathbf{F}_q so one of these is 0, and thus $N_q = 0$, which is uninteresting.

Proof. For $b \in \mathbf{F}_q^\times$, a nontrivial multiplicative character χ on \mathbf{F}_q^\times of order n , and an n -th root of unity ε in \mathbf{C} , the finite geometric series of n terms with ratio $\chi(b)/\varepsilon$ equals

$$1 + \frac{\chi(b)}{\varepsilon} + \left(\frac{\chi(b)}{\varepsilon}\right)^2 + \dots + \left(\frac{\chi(b)}{\varepsilon}\right)^{n-1} = \begin{cases} n, & \text{if } \chi(b) = \varepsilon, \\ 0, & \text{if } \chi(b) \neq \varepsilon, \end{cases}$$

so

$$\frac{1}{n} \left(1 + \frac{\chi(b)}{\varepsilon} + \left(\frac{\chi(b)}{\varepsilon}\right)^2 + \dots + \left(\frac{\chi(b)}{\varepsilon}\right)^{n-1} \right) = \begin{cases} 1, & \text{if } \chi(b) = \varepsilon, \\ 0, & \text{if } \chi(b) \neq \varepsilon, \end{cases}$$

which generalizes (2.1). Therefore

$$N_q = \sum_{\substack{a \in \mathbf{F}_q \\ \text{all } a+c_j \neq 0}} \prod_{i=1}^r \frac{1}{n_i} \left(1 + \frac{\chi_i(a+c_i)}{\varepsilon_i} + \left(\frac{\chi_i(a+c_i)}{\varepsilon_i}\right)^2 + \dots + \left(\frac{\chi_i(a+c_i)}{\varepsilon_i}\right)^{n_i-1} \right).$$

This sum over \mathbf{F}_q is missing terms at those a for which $a + c_j = 0$ for some j . For such an a , the product over $1 \leq i \leq r$ associated to it in the above formula would be 0 or $1/n_j$, so we can write N_q as a sum over all of \mathbf{F}_q by including an additional error term:

$$\begin{aligned} N_q &= \sum_{a \in \mathbf{F}_q} \prod_{i=1}^r \frac{1}{n_i} \left(1 + \frac{\chi_i(a+c_i)}{\varepsilon_i} + \left(\frac{\chi_i(a+c_i)}{\varepsilon_i}\right)^2 + \dots + \left(\frac{\chi_i(a+c_i)}{\varepsilon_i}\right)^{n_i-1} \right) + e \\ &= \frac{1}{n_1 \dots n_r} \sum_{a \in \mathbf{F}_q} \prod_{i=1}^r \left(1 + \frac{\chi_i(a+c_i)}{\varepsilon_i} + \left(\frac{\chi_i(a+c_i)}{\varepsilon_i}\right)^2 + \dots + \left(\frac{\chi_i(a+c_i)}{\varepsilon_i}\right)^{n_i-1} \right) + e, \end{aligned}$$

where $|e| \leq 1/n_1 + \dots + 1/n_r \leq r/2$ (since $n_i \geq 2$). Multiplying out all the sums,

$$\begin{aligned} N_q &= \frac{1}{n_1 \dots n_r} \sum_{a \in \mathbf{F}_q} \sum_{\substack{0 \leq t_i \leq n_i-1 \\ \text{for all } i}} \frac{\chi_1(a+c_1)^{t_1} \dots \chi_r(a+c_r)^{t_r}}{\varepsilon_1^{t_1} \dots \varepsilon_r^{t_r}} + e \\ &= \frac{1}{n_1 \dots n_r} \sum_{\substack{0 \leq t_i \leq n_i-1 \\ \text{for all } i}} \frac{1}{\varepsilon_1^{t_1} \dots \varepsilon_r^{t_r}} \sum_{a \in \mathbf{F}_q} \chi_1(a+c_1)^{t_1} \dots \chi_r(a+c_r)^{t_r} + e. \end{aligned}$$

$q - |\{a \in \mathbf{F}_q : g(a) \neq 0\}| \geq q - r$, which contradicts (A.1) if r is small, such as $r = 1$ ($f(x) = cx^n$) for any q or $r = 2$ ($f(x) = cx^n(x-1)^n$) for $q > 4$.

The inner term when all t_i are 0 is $\sum_{a \in \mathbf{F}_q} 1 = q$, so

$$\left| N_q - \frac{q}{n_1 \cdots n_r} \right| \leq \frac{1}{n_1 \cdots n_r} \sum_{\substack{0 \leq t_i \leq n_i - 1 \\ \text{some } t_i \neq 0}} \left| \sum_{a \in \mathbf{F}_q} \chi_1(a + c_1)^{t_1} \cdots \chi_r(a + c_r)^{t_r} \right| + \frac{r}{2}.$$

We will use (A.1) to show each inner sum over \mathbf{F}_q on the right side has magnitude at most $(r-1)\sqrt{q}$, which would give us what we want:

$$\begin{aligned} \left| N_q - \frac{q}{n_1 \cdots n_r} \right| &\leq \frac{1}{n_1 \cdots n_r} \sum_{\substack{0 \leq t_i \leq n_i - 1 \\ \text{some } t_i \neq 0}} ((r-1)\sqrt{q}) + \frac{r}{2} \\ &= \frac{1}{n_1 \cdots n_r} (n_1 \cdots n_r - 1)(r-1)\sqrt{q} + \frac{r}{2} \\ &< (r-1)\sqrt{q} + \frac{r}{2}. \end{aligned}$$

It remains to show

$$\left| \sum_{a \in \mathbf{F}_q} \chi_1(a + c_1)^{t_1} \cdots \chi_r(a + c_r)^{t_r} \right| \leq (r-1)\sqrt{q}$$

when $0 \leq t_i \leq n_i - 1$ with some t_i not 0. Since \mathbf{F}_q^\times is cyclic, its character group is cyclic: let χ be a generator of the character group of \mathbf{F}_q^\times and write $\chi_i = \chi^{m_i}$ for $m_i \in \mathbf{Z}^+$. Then

$$\begin{aligned} \sum_{a \in \mathbf{F}_q} \chi_1(a + c_1)^{t_1} \cdots \chi_r(a + c_r)^{t_r} &= \sum_{a \in \mathbf{F}_q} \chi(a + c_1)^{t_1 m_1} \cdots \chi(a + c_r)^{t_r m_r} \\ &= \sum_{a \in \mathbf{F}_q} \chi((a + c_1)^{t_1 m_1} \cdots (a + c_r)^{t_r m_r}) \\ &= \sum_{a \in \mathbf{F}_q} \chi(f(a)), \end{aligned}$$

where $f(x) = (x + c_1)^{t_1 m_1} \cdots (x + c_r)^{t_r m_r}$. This polynomial is monic with r distinct roots. In order to apply (A.1) to bound $|\sum_{a \in \mathbf{F}_q} \chi(f(a))|$, all that remains to be checked is that $f(x)$ is not a $(q-1)$ -th power in $\mathbf{F}_q[x]$ (since χ has order $q-1$). That is equivalent, since f is monic, to the root multiplicities $t_1 m_1, \dots, t_r m_r$ not all being multiples of $q-1$.

To have $q-1 \mid t_i m_i$ is the same as having $(q-1)/(q-1, m_i) \mid t_i$ since $(q-1)/(q-1, m_i)$ and $m_i/(q-1, m_i)$ are relatively prime. The order of χ is $q-1$ and the order of χ_i is n_i , so from $\chi_i = \chi^{m_i}$ we get $n_i = (q-1)/(q-1, m_i)$. Therefore if (and only if) $q-1 \mid t_i m_i$ we have $n_i \mid t_i$. Recalling that $0 \leq t_i \leq n_i - 1$, we can have $n_i \mid t_i$ only if $t_i = 0$. Since some t_i is not 0 this completes the proof that $f(x)$ is not an n -th power. \square
