Fast inversion of quasiseparable-Hessenberg-Vandermonde matrices

T.Bella, Y.Eidelman, I.Gohberg, V.Olshevsky E.Tyrtyshnikov

Abstract. Although Gaussian elimination uses $O(n^3)$ operations to invert an arbitrary matrix, matrices with a special Vandermonde structure can be inverted in only $O(n^2)$ operations by the fast Traub algorithm [T66]. It was noticed in [GO97] that with a minor modification of the Traub algorithm it can typically yield a very high accuracy.

The Traub algorithm has been carried over from Vandermonde matrices $V(x) = \left[ x_i^{j-1} \right]$ involving monomials to polynomial Vandermonde matrices $V_R(x) = \left[ r_{j-1}(x_i) \right]$ involving real orthogonal polynomials [CR93], [GO94], and the Szego polynomials [O01].

In this paper we consider a new more general class of polynomials that we suggest to call $H-(1,1)$-q/s polynomials. The new class is wide enough to include all of the above important special cases, e.g., monomials, real orthogonal polynomials and the Szego polynomials. We derive a fast $O(n^2)$ Traub-like algorithm to invert the associated $H-(1,1)$-q/s-Vandermonde matrices.

The class of quasiseparable matrices is garnering a lot of attention recently; it has been found to be useful in designing a number of fast algorithms. The derivation of our new Traub-like algorithm is also based on exploiting the quasiseparable order $(1,1)$ structure of the corresponding Hessenberg matrices (thus suggesting the name $H-(1,1)$-q/s polynomials). Finally, the encouraging results of the first numerical experiments are presented.

1. Introduction

1.1. Inversion of polynomial-Vandermonde matrices

For a given system of polynomials $R = \{r_0(x), r_1(x), \ldots, r_{n-1}(x)\}$ and set of nodes $x = (x_1, \ldots, x_n)$, the corresponding polynomial-Vandermonde matrix $V_R(x) = \left[ r_{j-1}(x_i) \right]$ is given by

$$V_R(x) = \begin{bmatrix}
  r_0(x_1) & r_1(x_1) & \cdots & r_{n-1}(x_1) \\
  r_0(x_2) & r_1(x_2) & \cdots & r_{n-1}(x_2) \\
  \vdots & \vdots & \ddots & \vdots \\
  r_0(x_n) & r_1(x_n) & \cdots & r_{n-1}(x_n)
\end{bmatrix}.
$$

We consider in this paper the problem of inversion of the matrix $V_R(x)$ for a given system of polynomials $R$ in terms of the recurrence relations they satisfy.

In the simplest case where $R = \{1, x, x^2, \ldots, x^{n-1}\}$, $V_R(x)$ reduces to a classical Vandermonde matrix and the inversion algorithm is due to Traub [T66]. Although generally considered to be numerically inaccurate, it was shown in [GO97] that a minor modification of the original Traub algorithm results in very good accuracy.

While the structure-ignoring approach of Gaussian elimination for inversion of $V_R(x)$ requires $O(n^3)$ operations, the special structure allows algorithms to be derived exploiting that structure, resulting in fast algorithms computing $n^2$ entries of the inverse in $O(n^2)$ operations. Previous work in deriving such fast algorithms for inversion of $V_R(x)$ for various special cases of the polynomial system $R$ are listed in Table 1.
1.2. A more general class of polynomials

In this paper, we consider a more general class of polynomials that contains all of those listed in Table 1 as special cases. For simplicity, we start the introduction with considering the class of polynomials that satisfy the fairly general recurrence relations

\[ r_k(x) = (\alpha_k x - \delta_k) \cdot r_{k-1}(x) - (\beta_k x + \gamma_k) \cdot r_{k-2}(x). \]  

(1.2)

To show that these recurrence relations generalize those satisfied by the special cases listed in Table 1, we list each system and corresponding recurrence relations in Table 2.

<table>
<thead>
<tr>
<th>Polynomial System $R$</th>
<th>Recurrence relations</th>
</tr>
</thead>
<tbody>
<tr>
<td>monomials</td>
<td>$r_k(x) = x \cdot r_{k-1}(x)$</td>
</tr>
<tr>
<td>Chebyshev polynomials</td>
<td>$r_k(x) = 2x \cdot r_{k-1}(x) - r_{k-2}(x)$</td>
</tr>
<tr>
<td>Real orthogonal polynomials</td>
<td>$r_k(x) = (\alpha_k x - \delta_k) r_{k-1}(x) - \gamma_k \cdot r_{k-2}(x)$</td>
</tr>
<tr>
<td>Szegő polynomials</td>
<td>$r_k(x) = \left( \frac{\beta_k}{\rho_k} x + \frac{\rho_k}{\rho_{k-1}} \frac{1}{\rho_k} \right) r_{k-1}(x) - \left( \frac{\rho_k}{\rho_{k-1}} - \frac{\rho_{k-1}}{\rho_k} \cdot x \right) r_{k-2}(x)$</td>
</tr>
</tbody>
</table>

Note: Typically the 2-term recurrence relations (7.10) are used for the Szegő polynomials in practice. It is convenient to use here the 3-term recurrence relations of [G48] to draw a theoretical connection to (1.2).

\[ r_k(x) = (\alpha_k x - \delta_k) r_{k-1}(x) - (\beta_k x + \gamma_k) r_{k-2}(x) \]

Table 2. Systems of polynomials and corresponding recurrence relations.

---

1In fact, the algorithm we derive is valid for a slightly larger class of polynomials than those satisfying these recurrence relations. This is the class of H-(1, 1)-q/s polynomials, named for their relation to quasiseparable matrices; see Definition 1.3 for the formal definition, and Section 4 for more details.
1.3. Matrix interpretation of recurrence relations (1.2)

The system of polynomials satisfying (1.2) is related to what we suggest to call a counterpart matrix,

$$A = \begin{bmatrix}
\frac{\alpha_1}{\gamma_1} & \frac{\alpha_2}{\gamma_2} & \frac{\alpha_3}{\gamma_3} & \cdots & \frac{\alpha_n}{\gamma_n} \\
\frac{1}{\alpha_1} & \frac{\delta_1}{\alpha_2} & \frac{\delta_2}{\alpha_3} & \cdots & \frac{\delta_{n-1}}{\alpha_n} \\
\frac{1}{\alpha_2} & \frac{\beta_1}{\alpha_3} & \frac{\beta_2}{\alpha_4} & \cdots & \frac{\beta_{n-2}}{\alpha_n} \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
0 & \frac{1}{\alpha_{n-1}} & \frac{\gamma_{n-1}}{\alpha_n} & \cdots & \frac{1}{\alpha_n}
\end{bmatrix}$$

(1.3)

via

$$r_k(x) = \alpha_1 \cdots \alpha_k \det(xI - A)_{(k \times k)}.$$  

(1.4)

That is, the polynomials $r_k(x)$ are (scaled) characteristic polynomials of the principal submatrices of the matrix $A$. Clearly, the matrix $A = [a_{ij}]$ is (i) upper Hessenberg, i.e., $i > j + 1$ implies $a_{ij} = 0$, and further (ii) it is irreducible, i.e., $a_{i+1,i} \neq 0$ for $i = 1, \ldots, n - 1$.

Two important special cases of polynomials $r_k(x)$ as in (1.4), and corresponding counterpart matrices $A$ are presented next.

**Example 1.1 (Real-orthogonal polynomials & tridiagonal matrices).** The three-term recurrence relations

$$r_k(x) = (\alpha_k x - \delta_k) r_{k-1}(x) - \gamma_k \cdot r_{k-2}(x)$$

satisfied by real-orthogonal polynomials (see Table 2) are easily seen to be a special case of (1.2) with $\beta_k = 0$. Secondly, taking $\beta_k = 0$ for each $k$, the matrix $A$ of (1.3) reduces to the tridiagonal matrix

$$A = \begin{bmatrix}
\frac{\alpha_1}{\gamma_1} & \frac{\alpha_2}{\gamma_2} & 0 & \cdots & 0 \\
\frac{1}{\alpha_1} & \frac{\delta_1}{\alpha_2} & \frac{\delta_2}{\alpha_3} & \cdots & \frac{\delta_{n-1}}{\alpha_n} \\
0 & \frac{1}{\alpha_2} & \frac{\gamma_{n-1}}{\alpha_n - 1} & 0 & \cdots \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & \frac{1}{\alpha_n - 1} & \frac{\gamma_n}{\alpha_n}
\end{bmatrix}.$$  

(1.5)

In this special tridiagonal case the relation (1.4) is classical in the theory of real orthogonal polynomials, see [SB92], theorems 3.6.3, 3.6.20.

**Example 1.2 (Szegő polynomials & unitary Hessenberg matrices).** Polynomials orthogonal on the unit circle, or Szegő polynomials, satisfy the recurrence relations\(^2\) (cf. with Table 2)

$$r_k(x) = \left(\frac{1}{\mu_k} x + \frac{1}{\rho_{k-1} \mu_k} \right) r_{k-1}(x) - \left(\frac{\rho_k}{\mu_{k-1}} \frac{1}{\mu_k} \right) r_{k-2}(x),$$  

(1.6)

see, e.g., [G48]. These recurrence relations are also a special case of (1.2) with

$$\alpha_k = \frac{1}{\mu_k}, \quad \delta_k = -\frac{1}{\mu_k \rho_{k-1}}, \quad \beta_k = \frac{\rho_{k-1}}{\mu_k}, \quad \gamma_k = 0.$$  

(1.7)

---

\(^2\)Here the complex numbers $\{\rho_0 := -1, \rho_1, \ldots, \rho_n\}$ such that $|\rho_k| \leq 1$ are referred to as called reflection coefficients, and $\mu_k := \sqrt{1 - |\rho_k|^2}$ if $|\rho_k| < 1$ and $\mu_k := 1$ if $|\rho_k| = 1$ are called complementary parameters.
Also, inserting the relations (1.7) into the matrix $A$ of (1.3) results in the well-known unitary Hessenberg matrix of the form

$$
A = \begin{bmatrix}
-\rho_1 \rho_0^* & -\rho_2 \mu_1 \rho_0^* & -\rho_3 \mu_2 \mu_1 \rho_0^* & \cdots & -\rho_{n-1} \mu_{n-2} \cdots \mu_1 \rho_0^* & -\rho_n \mu_{n-1} \cdots \mu_1 \rho_0^* \\
\mu_1 & -\rho_2 \mu_1^* & -\rho_3 \mu_2 \mu_1^* & \cdots & -\rho_{n-1} \mu_{n-2} \cdots \mu_2 \mu_1^* & -\rho_n \mu_{n-1} \cdots \mu_2 \mu_1^* \\
0 & \mu_2 & -\rho_3 \mu_2^* & \cdots & -\rho_{n-1} \mu_{n-2} \cdots \mu_3 \mu_2^* & -\rho_n \mu_{n-1} \cdots \mu_3 \mu_2^* \\
\vdots & \ddots & \ddots & \ddots & \ddots & \ddots \\
0 & \ldots & \cdots & 0 & \mu_{n-1} & -\rho_n \rho_{n-1} \\
0 & \ldots & \cdots & 0 & \mu_{n-1} & -\rho_n \rho_{n-1}
\end{bmatrix} \quad (1.8)
$$

Again, the relation (1.4) connecting the Szego polynomials (1.6) and the unitary Hessenberg matrices (1.8) is well-known, see, e.g., [O01] and the references therein.

The tridiagonal (1.5), unitary Hessenberg (1.8) and counterpart (1.3) matrices are special cases of a more general class of matrices, defined next.

1.4. Main tool: quasiseparable matrices and polynomials

**Definition 1.3.** (Quasiseparable matrices and polynomials)

- A matrix $A$ is called $H$-(1,$n$)-quasiseparable if (i) it is upper Hessenberg, and (ii) max(rank $A_{12}$) = $n$ where the maximum is taken over all symmetric partitions of the form
  $$A = \begin{bmatrix} * & A_{12} \\ * & * \end{bmatrix}$$

- Let $A = [a_{ij}]$ be an irreducible (i.e., $a_{i+1,i} \neq 0$), $H$-(1,1)-quasiseparable matrix with $\alpha_i = 1/a_{i+1,i}$. Then the system of polynomials related to $A$ via
  $$r_k(x) = \alpha_1 \cdots \alpha_k \det (xI - A)_{(k \times k)}$$

  is called a system of Hessenberg-(1,1)-quasiseparable polynomials, or $H$-(1,1)-q/s polynomials.

**Remark 1.4.** The counterpart matrix $A$ of (1.3) is irreducible $H$-(1,1)-quasiseparable. Indeed, one can see that in any partition $A = \begin{bmatrix} * & A_{12} \\ * & * \end{bmatrix}$ the $(k-1)$-st column $A_{12}(\cdot,k-1)$ and the $k$-th column $A_{12}(\cdot,k)$ of the matrix $A_{12}$ are scalar multiples of each other:

$$A_{12}(\cdot,k) = \frac{\beta_k \gamma_k}{\alpha_k \gamma_k} A_{12}(\cdot,k-1).$$

E.g., inspect the $2 \times (n-2)$ matrix

$$A_{12} = \begin{bmatrix}
\frac{\alpha_1}{\alpha_2} \beta_2 + \gamma_2 \left( \frac{\alpha_3}{\alpha_2} \right) & \frac{\alpha_1}{\alpha_2} \beta_2 + \gamma_2 \left( \frac{\alpha_3}{\alpha_2} \right) & \frac{\alpha_1}{\alpha_2} \beta_2 + \gamma_2 \left( \frac{\alpha_3}{\alpha_2} \right) & \frac{\alpha_1}{\alpha_2} \beta_2 + \gamma_2 \left( \frac{\alpha_3}{\alpha_2} \right) & \frac{\alpha_1}{\alpha_2} \beta_2 + \gamma_2 \left( \frac{\alpha_3}{\alpha_2} \right) & \frac{\alpha_1}{\alpha_2} \beta_2 + \gamma_2 \left( \frac{\alpha_3}{\alpha_2} \right) & \cdots \\
\left( \frac{\alpha_1}{\alpha_2} + \frac{\beta_3 + \gamma_3}{\alpha_3} \right) \beta_3 + \gamma_3 & \left( \frac{\alpha_1}{\alpha_2} + \frac{\beta_3 + \gamma_3}{\alpha_3} \right) \beta_3 + \gamma_3 & \left( \frac{\alpha_1}{\alpha_2} + \frac{\beta_3 + \gamma_3}{\alpha_3} \right) \beta_3 + \gamma_3 & \left( \frac{\alpha_1}{\alpha_2} + \frac{\beta_3 + \gamma_3}{\alpha_3} \right) \beta_3 + \gamma_3 & \left( \frac{\alpha_1}{\alpha_2} + \frac{\beta_3 + \gamma_3}{\alpha_3} \right) \beta_3 + \gamma_3 & \left( \frac{\alpha_1}{\alpha_2} + \frac{\beta_3 + \gamma_3}{\alpha_3} \right) \beta_3 + \gamma_3 & \cdots
\end{bmatrix}.$$

Hence polynomials satisfying the recurrence relations (1.2) are a special case of $H$-(1,1)-q/s polynomials.

The two matrix examples of subsection 1.3 indicate that tridiagonal matrices and unitary Hessenberg matrices are special counterpart matrices implying that the class of $H$-(1,1)-q/s polynomials is wide enough to include important classes of real orthogonal polynomials and Szegö polynomials as special cases.

1.5. Main problem: Inversion of $H$-(1,1)-q/s-Vandermonde matrices

In this paper we extend the Traub algorithm to a polynomial-Vandermonde matrix $V_R(x)$ whose defining polynomial system $R$ is a $H$-(1,1)-q/s system. The new algorithm generalizes the corresponding algorithms for monomials, real orthogonal polynomials, and Szegö polynomials, which are themselves special cases of $H$-(1,1)-q/s polynomials. In particular, it applies to another important special case when polynomials $R$ satisfy the general recurrence relations (1.2).
1.6. Structure of the paper

In Section 2 an inversion formula valid for a general system of polynomials (although expensive in general) is presented. The formula presented there reduces the problem of inversion of $V_R(x)$ to that of evaluating the so-called associated polynomials $\hat{R}$ corresponding to the polynomial system $R$. In Section 3 a relation between the polynomial systems $R$ and $\hat{R}$ is presented in terms of their confederate matrices. This relation suggests a procedure for evaluating the associated polynomials $\hat{R}$. In Section 4 quasiseparable matrices are defined, and a conversion from the polynomial language (i.e. polynomials satisfying (1.2)) to the matrix language (i.e. generators of a quasiseparable matrix) is given. In Section 5, perturbed recurrence relations are presented for the associated polynomials $\hat{R}$. It is these recurrence relations that allow the computational speedup that results in a fast $O(n^2)$ algorithm, presented formally in Section 7. Three different sets of recurrence relations are given, two generalizing known formulas for real orthogonal polynomials and Szegő polynomials, and a third the produces new formulas for these cases. In Section 6, a fast algorithm for computing the coefficients of the master polynomial is presented. This is required in step 2 of Algorithm 3.2. In Section 7 the algorithm is presented in full detail. The reduction in the special cases of monomials, real orthogonal polynomials, and Szegő polynomials is examined in detail as well. In Section 8, several theorems are presented that completely characterize systems of $H$-(1,1)-q/s polynomials in terms of the Hessenberg, order (1,1) quasiseparable matrices they correspond to, and vice versa. Section 9 consists of some results of numerical experiments with the proposed algorithm, and conclusions are offered in the final section. Some proofs have additionally been postponed to the appendix, which follows the conclusions.

2. Inversion formula

In this section we present a formula and overview of the suggested algorithm used to invert a polynomial-Vandermonde matrix as in (1.1). Such a matrix is completely determined by $n$ polynomials $R = \{r_0(x), \ldots, r_{n-1}(x)\}$ and $n$ nodes $x = (x_1, \ldots, x_n)$. Then the desired inverse $V_R(x)^{-1}$ is given by the formula

$$V_R(x)^{-1} = \tilde{I} \cdot V^T_R(x) \cdot \text{diag}(c_1, \ldots, c_n),$$

(2.1)

(see [O98], [O01]) where

$$c_i = \prod_{k=1 \atop k \neq i}^{n} (x_k - x_i)^{-1},$$

(2.2)

$\tilde{I}$ is the antidiagonal matrix

$$\tilde{I} = \begin{bmatrix} 0 & \cdots & 0 & 1 \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \ddots & \ddots & 1 \\ 1 & 0 & \cdots & 0 \end{bmatrix},$$

(2.3)

and $\hat{R}$ is the system of associated (generalized Horner) polynomials, defined as follows: if we define the master polynomial $P(x)$ by $P(x) = (x-x_1) \cdots (x-x_n)$, then for the polynomial system $R = \{r_0(x), \ldots, r_{n-1}(x), P(x)\}$, the associated polynomials $\hat{R} = \{\hat{r}_0(x), \ldots, \hat{r}_{n-1}(x), P(x)\}$ are those satisfying the relations

$$\frac{P(x) - P(y)}{x - y} = \sum_{k=0}^{n-1} r_k(x) \cdot \hat{r}_{n-k-1}(y),$$

(2.4)

see [KO97]. This can be seen as a generalization of the Horner polynomials associated with the monomials, cf. with the discussion in section 3.3 below.

This discussion gives a relation between the inverse $V_R(x)^{-1}$ and the polynomial-Vandermonde matrix $V_R(x)$, where $\hat{R}$ is the system of polynomials associated with $R$. To use this in order to invert $V_R(x)$, one needs to evaluate the polynomials $\hat{R}$ at the nodes $x$ to form $V^T_R(x)$, and a procedure for doing this is suggested by their confederate matrices defined next.
3. Confederate matrix interpretation of associated polynomials $\widehat{R}$ involved in the inversion formula (2.1)

3.1. Definition for the confederate matrix

We next give the definition of the confederate matrix of a polynomial with respect to a given system of polynomials. Let polynomials $R = \{r_0(x), r_1(x), \ldots, r_n(x)\}$ with $\deg(r_k) = k$ be specified by the general recurrence relations

$$r_k(x) = (a_k x - a_{k-1,k}) \cdot r_{k-1}(x) - a_{k-2,k} \cdot r_{k-2}(x) - \cdots - a_{0,k} \cdot r_0(x)$$

for $k = 1, \ldots, n$. Following [MB79], define for the polynomial

$$P(x) = P_0 \cdot r_0(x) + P_1 \cdot r_1(x) + \cdots + P_{n-1} \cdot r_{n-1}(x) + P_n \cdot r_n(x)$$

its confederate matrix

$$C_R(P) = \begin{bmatrix}
   a_{00} & a_{01} & \cdots & a_{0n} \\
   a_{10} & a_{11} & \cdots & a_{1n} \\
   \vdots & \vdots & \ddots & \vdots \\
   0 & 0 & \cdots & \frac{1}{a_k}
\end{bmatrix}
\begin{bmatrix}
P_0 \\
P_1 \\
\vdots \\
P_n-1
\end{bmatrix} + \begin{bmatrix}
   \frac{1}{a_{00}} \\
   \frac{1}{a_{11}} \\
   \vdots \\
   \frac{1}{a_{n-1,n}}
\end{bmatrix}

$$

with respect to the polynomial system $R$. Notice that the coefficients of the recurrence relations for the $k^{th}$ polynomial $r_k(x)$ from (3.1) are contained in the $k^{th}$ column of $C_R(r_n)$, as the highlighted column shows. Notice also that in the special case $P(x) = r_n(x)$, the second matrix in (3.3) vanishes. We refer to [MB79] for many useful properties of the confederate matrix and only recall here that $\det(xI - C_R(P)) = P(x)/(a_0 \cdot a_1 \cdot \ldots \cdot a_n)$, and that similarly, the characteristic polynomial of the $k \times k$ leading submatrix of $C_R(P)$ is equal to $r_k(x)/a_0 \cdot a_1 \cdot \ldots \cdot a_k$.

**Example 3.1.** It will be convenient, for future reference, to collect in the next table several special cases of confederate matrices.

<table>
<thead>
<tr>
<th>Recurrence Relations of $R$</th>
<th>Confederate matrix $C_R(r_n)$</th>
</tr>
</thead>
</table>
| $r_k(x) = x r_{k-1}(x)$    | $\begin{bmatrix}

   0 & \vdots & \ddots & \vdots \\
   0 & \vdots & \ddots & 1 \\
   0 & \cdots & 0 & 1
\end{bmatrix}$ |

**Table 3.** Polynomial systems and corresponding confederate matrices.
Confederate matrix $C_R(r_n)$

$C_R(P) = \begin{bmatrix}
\frac{\delta_1}{\alpha_1} & \frac{\beta_1}{\alpha_2} \\
\frac{1}{\alpha_1} & \frac{\beta_2}{\alpha_2}
\end{bmatrix}$

$C_{\tilde{R}}(P) = \begin{bmatrix}
\frac{\beta_n}{\alpha_n} + \frac{\beta_{n-1}}{\alpha_{n-1}} & \frac{\beta_n}{\alpha_n} \\
\frac{1}{\alpha_n} & \frac{\beta_n}{\alpha_n}
\end{bmatrix}$

### 3.2. The relationship between $C_R(P)$ (defining $V_R(x)$) & $C_{\tilde{R}}(P)$ (defining $V_{\tilde{R}}(x)$ used in the inversion formula)

The motivation for considering confederate matrices is that they will allow the computation of the polynomials associated with the given system of polynomials. The confederate matrices of $R$ and $\tilde{R}$ are related by

$$C_{\tilde{R}}(P) = \tilde{I} \cdot C_R(P)^T \cdot \tilde{I}. \quad (3.4)$$

(see [O98], [O01]). The passage from $C_R(P)$ to $C_{\tilde{R}}(P)$ in (3.4) can be seen as a transposition across the antidiagonal, or a pertransposition, or more visually,

$C_R(P) = \begin{bmatrix} a \\ b \end{bmatrix}$

Pertransposition

$\begin{bmatrix} b \\ a \end{bmatrix} = C_{\tilde{R}}(P)$

Table 4. Polynomial systems and corresponding confederate matrices.
As an example, consider for a moment the $5 \times 5$ Hessenberg confederate matrix

$$C_R(P) = \begin{bmatrix}
\alpha_{15} & \frac{P_0}{P_{5,05}} & \alpha_{15} & \frac{P_5}{P_{5,05}} & \alpha_{15} & \frac{P_{15}}{P_{5,05}} \\
\frac{1}{\alpha_{15}} & \frac{P_0}{P_{5,05}} & \frac{1}{\alpha_4} & \frac{P_5}{P_{5,05}} & \frac{1}{\alpha_3} & \frac{P_{15}}{P_{5,05}} \\
0 & \frac{1}{\alpha_3} & \frac{1}{\alpha_2} & \frac{1}{\alpha_1} & \frac{1}{\alpha_4} & \frac{1}{\alpha_5} \\
0 & 0 & \frac{1}{\alpha_3} & \frac{1}{\alpha_2} & \frac{1}{\alpha_1} \\
0 & 0 & 0 & \frac{1}{\alpha_4} & \frac{1}{\alpha_5}
\end{bmatrix}$$

(3.5)

It corresponds to a system $R$ of polynomials satisfying (3.1). From (3.4) above, the system of polynomials associated with $R$, denoted by $\hat{R} = \{\hat{r}_0(x), \hat{r}_1(x), \ldots, \hat{r}_5(x)\}$, has confederate matrix

$$C_{\hat{R}}(P) = \begin{bmatrix}
\alpha_{15} & \frac{P_0}{P_{5,05}} & \alpha_{15} & \frac{P_5}{P_{5,05}} & \alpha_{15} & \frac{P_{15}}{P_{5,05}} \\
\frac{1}{\alpha_{15}} & \frac{P_0}{P_{5,05}} & \frac{1}{\alpha_4} & \frac{P_5}{P_{5,05}} & \frac{1}{\alpha_3} & \frac{P_{15}}{P_{5,05}} \\
0 & \frac{1}{\alpha_3} & \frac{1}{\alpha_2} & \frac{1}{\alpha_1} & \frac{1}{\alpha_4} & \frac{1}{\alpha_5} \\
0 & 0 & \frac{1}{\alpha_3} & \frac{1}{\alpha_2} & \frac{1}{\alpha_1} \\
0 & 0 & 0 & \frac{1}{\alpha_4} & \frac{1}{\alpha_5}
\end{bmatrix}.$$

(3.6)

In accordance with (2.1), the main computational burden is to compute $V_{\hat{R}}$, i.e. to evaluate $n$ polynomials $\{\hat{r}_k(x)\}_{k=0}^{n-1}$ at $n$ points $\{x_k\}_{k=0}^{n}$. Using (3.6) to accomplish this is expensive in the general case, since it leads to the full $n$-term recurrence relations, for instance the highlighted column in (3.6) implies that the recurrence relations for $\hat{r}_4(x)$ are given by

$$\hat{r}_4(x) = \frac{\alpha_1}{\alpha_2} \cdot x \cdot \hat{r}_3(x) - \frac{\alpha_1}{\alpha_4} \cdot \hat{r}_2(x) - \frac{\alpha_1}{\alpha_3} \cdot \hat{r}_1(x) + \frac{\alpha_1}{\alpha_5} (a_{1,5} + \frac{P_1}{P_5}) \cdot \hat{r}_0(x)$$

(3.7)

Additionally, the coefficients $P_i$ of the master polynomial $P(x)$ decomposed into the $R$ basis must be computed; that is, $\{P_0, \ldots, P_n\}$ such that

$$\prod_{k=1}^{n} (x - x_k) = P_0 r_0(x) + P_1 r_1(x) + \cdots + P_{n-1} r_{n-1}(x) + P_n r_n(x).$$

(3.8)

as they are present in the recurrence relations defining $\hat{r}_k(x)$.

All of this allows us to present the Traub-like inversion algorithm next.

**Algorithm 3.2. [Traub-like inversion algorithm]**

1. **Compute the entries of $\text{diag}(c_1, \ldots, c_n)$ via (2.2).**
2. **Compute the coefficients $\{P_0, P_1, \ldots, P_{n-1}\}$ of the master polynomial $P(x)$ as in (3.8).**
3. **Evaluate the $n$ polynomials of $\hat{R}$ with confederate matrix specified via (3.4) at the $n$ nodes $x_k$ to form $V_{\hat{R}}(x)$.**
4. **Compute the inverse $V_{\hat{R}}(x)^{-1}$ via (2.1).**

We next present the simplest special case, when the polynomial system $R$ is a system of monomials, and how the algorithm resulting is the classical Traub algorithm with complexity $O(n^2)$.

### 3.3. Example: monomial bases & the Horner recursion, and the classical Traub algorithm

Monomials $R = \{1, x, x^2, \ldots, x^{n-1}\}$ satisfy the obvious recurrence relations $x^k = x \cdot x^{k-1}$ and hence the confederate matrix (3.3) becomes

$$C_R(P) = \begin{bmatrix}
0 & 0 & \cdots & 0 & -P_0 \\
1 & 0 & \cdots & 0 & -P_1 \\
& & & \ddots & \vdots \\
0 & \cdots & 0 & 1 & -P_{n-1}
\end{bmatrix}$$

(3.9)

which is the well-known companion matrix.
Using the pertransposition rule (3.4) of section 3.2, we obtain the confederate matrix

\[
C_R(\tilde{r}_n) = \begin{bmatrix}
-P_{n-1} & -P_{n-2} & \cdots & -P_1 & -P_0 \\
1 & 0 & \cdots & 0 & 0 \\
0 & 1 & \ddots & \vdots & 0 \\
\vdots & \ddots & \ddots & 0 & \vdots \\
0 & \cdots & 0 & 1 & 0
\end{bmatrix}
\]  

(3.10)

for the associated polynomials \(\tilde{r}_k(x)\). Using the formula (3.1), we read from the matrix (3.10) the familiar Horner recurrence relations

\[
\tilde{r}_0(x) = 1, \quad \tilde{r}_k(x) = x\tilde{r}_{k-1}(x) + P_n - k.
\]

(3.11)

To sum up, in case of monomials our approach yields the classical \(O(n^2)\) Traub algorithm that will be generalized in the rest of the paper. The generalization will be using the concept of a quasiseparable matrix defined next.

4. Main tool: Quasiseparable matrices and polynomials

4.1. Quasiseparable matrices and polynomials.

4.1.1. Quasiseparable matrices. We begin with the rank definition of quasiseparability; an equivalent definition will be given afterwards.

**Definition 4.1 (Rank definition for H-(1, 1)-quasiseparable matrices).** A matrix \(A\) is called \(H-(1, n)\)-quasiseparable if (i) it is Hessenberg, and (ii) \(\max(\text{rank} A_{12}) = n\) and \(\max(\text{rank} A_{21}) = 1\), where the maximum is taken over all symmetric partitions of the form

\[
A = \begin{bmatrix}
* & A_{12} \\
A_{21} & *
\end{bmatrix}
\]

(4.1)

**Example 4.2.** Each of the confederate matrices in Table 4 is \(H-(1, 1)\)-quasiseparable.

**Tridiagonal matrix:** Indeed, if \(A\) is tridiagonal as in (1.5), then the submatrix \(A_{12}\) has the form

\[
A_{12} = \begin{bmatrix}
0 & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 \\
\frac{\alpha_k}{\beta_k} & 0 & \cdots & 0
\end{bmatrix}
\]

which can easily be observed to have rank one.

**Unitary Hessenberg matrix:** Also, if \(A\) is a unitary Hessenberg matrix as in (1.8), then for instance the corresponding submatrix \(A_{12}\) of size \(3 \times (n - 4)\)

\[
A_{12} = \begin{bmatrix}
-\rho_1 \mu_3 \mu_2 \rho_0^* & -\rho_2 \mu_3 \mu_2 \rho_1^* & \cdots & -\rho_{n-1} \mu_3 \mu_2 \rho_0^* \\
-\rho_1 \mu_3 \mu_2 \rho_1^* & -\rho_2 \mu_3 \mu_2 \rho_2^* & \cdots & -\rho_{n-1} \mu_3 \mu_2 \rho_1^* \\
-\rho_1 \mu_3 \mu_2 \rho_2^* & -\rho_2 \mu_3 \mu_2 \rho_3^* & \cdots & -\rho_{n-1} \mu_3 \mu_2 \rho_2^*
\end{bmatrix}
\]

clearly has rank one. Thus, since tridiagonal matrices and unitary Hessenberg matrices have this special structure, they are quasiseparable of order one.

**Counterpart matrix:** The counterpart matrix \(A\) of (1.3) is irreducible \(H-(1, 1)\)-quasiseparable. Indeed, one can see that in any partition \(A = \begin{bmatrix} * & A_{12} \\ A_{21} & *
\end{bmatrix}\) the \((k - 1)\)-st column \(A_{12}(; k)\) and the \(k\)-th column \(A_{12}(; k)\) of the matrix \(A_{12}\) are scalar multiples of each other:

\[
A_{12}(; k) = \frac{\beta_{k+2}}{\alpha_{k+2}} A_{12}(; k - 1).
\]

E.g., inspect the \(2 \times (n - 2)\) matrix

\[
A_{12} = \begin{bmatrix}
\frac{\alpha_1}{\beta_3} \beta_2 + \gamma_2 & \frac{\alpha_1}{\beta_3} \beta_2 + \gamma_2 & \frac{\alpha_1}{\beta_3} \beta_2 + \gamma_2 & \frac{\alpha_1}{\beta_3} \beta_2 + \gamma_2 \\
\frac{\alpha_2}{\beta_3} \beta_3 + \gamma_3 & \frac{\alpha_2}{\beta_3} \beta_3 + \gamma_3 & \frac{\alpha_2}{\beta_3} \beta_3 + \gamma_3 & \frac{\alpha_2}{\beta_3} \beta_3 + \gamma_3 \\
\frac{\alpha_3}{\beta_3} \beta_4 + \gamma_3 & \frac{\alpha_3}{\beta_3} \beta_4 + \gamma_3 & \frac{\alpha_3}{\beta_3} \beta_4 + \gamma_3 & \frac{\alpha_3}{\beta_3} \beta_4 + \gamma_3 \\
\frac{\alpha_4}{\beta_3} \beta_5 + \gamma_3 & \frac{\alpha_4}{\beta_3} \beta_5 + \gamma_3 & \frac{\alpha_4}{\beta_3} \beta_5 + \gamma_3 & \frac{\alpha_4}{\beta_3} \beta_5 + \gamma_3
\end{bmatrix}.
\]
We present next an alternate definition of quasiseparable matrices that is equivalent to Definition 4.1 when the matrix is additionally upper Hessenberg.

**Definition 4.3 (Generator definition for H-(1,1)-quasiseparable matrices).** A matrix $A$ is called H-(1, $n$)-quasiseparable if (i) it is Hessenberg, and (ii) it can be represented in the form

$$A = \begin{pmatrix}
\vdots & \vdots \\
\ddots & \ddots & \ddots \\
& d_i & g_i b_{ij} h_j \\
& & \ddots & \ddots & \ddots \\
& & & \ddots & \ddots & \ddots \\
& & & & \ddots & \ddots \\
& & & & & \ddots \\
& & & & & & 0 \\
& & & & & & p_n q_{n-1} \\
& & & & & & d_n \\
\end{pmatrix}$$

where $b_{ij}^* = b_{i+1} \cdots b_{j-1}$ for $j > i + 1$ and $b_{ij}^* = 1$ for $j = i + 1$. The elements

$$\{p_k, q_k, d_k, g_k, b_k, h_k\},$$

called the generators of the matrix $A$, are matrices of sizes

<table>
<thead>
<tr>
<th></th>
<th>$p_k$</th>
<th>$q_k$</th>
<th>$d_k$</th>
<th>$g_k$</th>
<th>$b_k$</th>
<th>$h_k$</th>
</tr>
</thead>
<tbody>
<tr>
<td>sizes</td>

<td>$k \in [2, n]$</td>
</tr>
</tbody>
</table>

subject to $\max_k r''_k = n$.

**4.1.2. Quasiseparable polynomials.**

**Definition 4.4 (H-(1,1)-Quasiseparable polynomials).** Let $A = [a_{ij}]$ be an irreducible (i.e., $a_{i+1,i} \neq 0$), H-(1,1)-quasiseparable matrix with $a_{i+1,i} = 1/a_{i+1,i}$. Then the system of polynomials related to $A$ via

$$r_k(x) = \alpha_1 \cdots \alpha_k \det (xI - A)_{(k \times k)},$$

is called a system of Hessenberg-(1,1)-quasiseparable polynomials, or H-(1,1)-q/s polynomials.

In brief, H-(1,1)-q/s polynomials are those whose confederate matrices are H-(1,1)-q/s.

**Example 4.5.** The example 4.2 means that the class of H-(1,1)-q/s polynomials includes, as special cases two important classical polynomial classes of (i) real orthogonal polynomials; (ii) Szegő polynomials; as well as (iii) a fairly general class of polynomials satisfying (1.2).

**Remark 4.6.** It is useful to note that the definition 4.3 and the formula (3.1) imply that H-(1,1)-quasiseparable polynomials satisfy $n$-term recurrence relations

$$r_k(x) = \frac{1}{p_{k+1} q_k} \left[ (x - d_k) r_{k-1}(x) - \sum_{j=0}^{k-2} (g_{j+1} b_{j+1, k} h_k r_j(x)) \right]$$

that use only $O(n)$ parameters, i.e., generators. The formula (4.2) is not sparse and hence expensive. We postpone presenting the more computationally efficient formulas for H-(1,1)-quasiseparable polynomials till section 8 since they are not needed for the derivation of the Traub-like algorithm.

**4.1.3. Conversion of recurrence relation coefficients into quasiseparable generators.** In the rest of the paper we will be deriving the algorithm for inversion of H-(1,1)-q/s-Vandermonde matrices using generators. However, in many examples, see, e.g., in Table 4, the polynomials are often defined not by the generators but via recurrence relations (1.2). The next theorem shows how to convert the latter into the former. The formal proof is postponed to the appendix (see page 24).
Theorem 4.7 (Recurrence relation coefficients ⇒ quasiseparable generators). Let \( R = \{r_0(x), \ldots, r_n(x)\} \) be a system of polynomials s.t. \( \text{deg}(r_k) = k \) and denote by \( C_R(r_n) \) the confederate matrix of \( r_n(x) \) with respect to \( R \). Suppose \( R \) satisfies the recurrence relations (1.2). Then \( C_R(r_n) \) is an irreducible Hessenberg-(1,1)-quasiseparable matrix with generators

\[
\begin{align*}
    d_1 &= \frac{\delta_1}{\alpha_1}, & d_k &= \frac{\delta_k}{\alpha_k} + \frac{\beta_k}{\alpha_k-1\alpha_k}, & k &= 2, \ldots, n \\
    p_{k+1}q_k &= \frac{1}{\alpha_k}, & g_k &= \frac{d_k\beta_{k+1} + \gamma_{k+1}}{\alpha_{k+1}}, & k &= 1, \ldots, n-1 \\
    b_k &= \frac{\beta_{k+1}}{\alpha_{k+1}}, & h_k &= 1, & k &= 2, \ldots, n
\end{align*}
\]

We are ready to start the derivation of the main algorithm.

4.2. Inversion problem: a quasiseparable confederate matrix interpretation

4.2.1. Computing the associated polynomials. In this section we specify the general procedure of Section 3.2 to quasiseparable confederate matrices. Given a polynomial system satisfying recurrence relations (1.2), the coefficients \( \{\alpha_k, \delta_k, \beta_k, \gamma_k\} \) can be used in Theorem 4.7 to generate an irreducible Hessenberg (1,1)-quasiseparable matrix of the form shown in Definition 4.3. Next, considering the confederate matrix with respect to the master polynomial \( P(x) = \prod (x - x_k) \) defined by the nodes \( x_k, k = 1, \ldots, n \), we have

\[
C_R(P) =
\begin{bmatrix}
    d_1 & g_1 b_{1j} h_j & & \\
    p_2 q_1 & & & -\frac{1}{P_0} \\
    & \ddots & \ddots & \\
    0 & \cdots & 0 & P_{n-1}
\end{bmatrix}
\]

Applying (3.4) gives us the confederate matrix for the associated polynomials as

\[
C_R(P) =
\begin{bmatrix}
    d_n & g_{n-j} b_{n-j,n-i} h_{n-i} & & \\
    p_n q_{n-1} & & & -\frac{1}{P_0} \\
    & \ddots & \ddots & \\
    0 & \cdots & 0 & P_{n-1}
\end{bmatrix}
\]

From this last equation we can see that the \( n \)-term recurrence relations satisfied by the associated polynomials \( \widehat{R} \) are given by

\[
\widehat{r}_k(x) = \frac{1}{p_{k+1}q_k} \left[ (x - \widehat{d}_k)\widehat{r}_{k-1}(x) - \sum_{j=0}^{k-2} \left( g_{j+1} \widehat{b}_{j+1,k} h_{j} \widehat{r}_j(x) \right) - \frac{P_{n-k}}{P_n} \widehat{r}_0(x) \right]
\]
where, in order to simplify the formulas, we introduce the notation
\[
\hat{p}_k = q_{n-k+1}, \quad \hat{q}_k = p_{n-k+1}, \quad \hat{d}_k = d_{n-k+1}, \quad \hat{g}_k = h_{n-k+1}, \quad \hat{b}_k = b_{n-k+1}, \quad \hat{h}_k = g_{n-k+1}.
\]
(4.9)

Having found explicit \( n \)-term recurrence relations for the system of polynomials associated with the given system satisfying (1.2), the next goal is to find sparse recurrence relations. The motivation is that the \( n \)-term recurrence relations are slow; they lead to \( O(n^3) \) algorithms, while two- and three-term recurrence relations lead to \( O(n^2) \) algorithms.

5. Perturbed recurrence relations (to be used in step 3 of Algorithm 3.2)

In this section we consider the case where \( R \) is a system of H-(1,1)-\( q/s \) polynomials, and we derive sparse recurrence relations for the associated system of polynomials. For quasiseparable-(1,1)-polynomials themselves, such recurrence relations are derived in [EGO05]. Obtaining these formulas for the leading minors of \( C_R(P) \) of the form shown in (4.7) is not immediate, as the second term now affects each column, and the result is that the leading submatrices are now of order (1,2), as opposed to those of the form shown in (4.6), which are all of order (1,1).

We begin with recurrence relations generalizing classical two- and three-term recurrence relations; that is, the two-term recurrence relations satisfied by the Szegö polynomials, and the three-term recurrence relations satisfied by both the Szegö polynomials and real orthogonal polynomials. Special conditions on the generators must be satisfied for these two results to be applicable in more general cases.

**Theorem 5.1 (Three-term recurrence relations).** Let \( R = \{r_0(x), \ldots, r_{n-1}(x), P(x)\} \) be a system of H-(1,1)-\( q/s \) polynomials corresponding to an irreducible Hessenberg-(1,1)-quasiseparable matrix of size \( n \times n \) with generators \( \{p_k, q_k, d_k, g_k, b_k, h_k\} \) as in Definition 4.3, with the convention that \( g_n = 1, b_n = 0 \). Suppose further that \( g_k \neq 0 \) for \( k = 1, \ldots, n-1 \). Then the system of polynomials \( \hat{R} \) associated with \( R \) satisfies the recurrence relations below.

**Limitation:** \( g_k \neq 0, k = 1, \ldots, n-1 \)

\[
\hat{r}_0(x) = P_n, \quad \hat{r}_1(x) = \frac{1}{p_{2q_1}} (x - \hat{d}_1) \hat{r}_0(x) + \frac{1}{p_{2q_1}} P_{n-1}
\]
\[
\hat{r}_k(x) = (\hat{\alpha}_k x - \hat{\delta}_k) \cdot \hat{r}_{k-1}(x) - (\hat{\beta}_k + \hat{\gamma}_k) \cdot \hat{r}_{k-2}(x) + \hat{\alpha}_k P_{n-k} - \hat{\beta}_k P_{n-k+1}, \quad k = 2, \ldots, n-1
\]
(5.1)

where
\[
\hat{\alpha}_k = \frac{1}{p_{k+1}q_k}, \quad \hat{\delta}_k = \frac{1}{p_{k+1}q_k} \left( \hat{d}_k - \frac{\hat{p}_k \hat{q}_{k-1} \hat{h}_k \hat{b}_{k-1}}{\hat{h}_{k-1}} \right)
\]
(5.2)
\[
\hat{\beta}_k = \frac{1}{p_{k+1}q_k} \frac{\hat{h}_k \hat{b}_{k-1}}{\hat{h}_{k-1}}, \quad \hat{\gamma}_k = \frac{1}{p_{k+1}q_k} \frac{\hat{h}_k}{\hat{h}_{k-1}} \left( \hat{h}_{k-1} \hat{g}_{k-1} - \hat{a}_{k-1} \hat{b}_{k-1} \right),
\]
(5.3)

and the coefficients \( P_k, k = 0, \ldots, n \) are as defined in (3.8).

The proof is given in the appendix, see page 25. The following notations will be used to present the two-term recurrence relations.

\[
u_k(x) = (x - \hat{d}_k) + \frac{\hat{g}_k \hat{h}_k}{\hat{b}_k}, \quad \nu_k = \frac{\hat{p}_k + 1}{\hat{b}_k} \frac{\hat{q}_k}{\hat{h}_k}.
\]
(5.4)

**Theorem 5.2 (Szegö-type recurrence relations).** Let \( R = \{r_0(x), \ldots, r_{n-1}(x), P(x)\} \) be a system of H-(1,1)-\( q/s \) polynomials corresponding to an irreducible Hessenberg-(1,1)-quasiseparable matrix of size \( n \times n \) with generators \( \{p_k, q_k, d_k, g_k, b_k, h_k\} \) as in Definition 4.3, with the convention that \( g_n = 0, b_n = 1 \). Suppose further that \( b_k \neq 0 \) for \( k = 2, \ldots, n-1 \). Then the system of polynomials \( \hat{R} \) associated with \( R \) satisfies the recurrence relations below.

**Limitation:** \( b_k \neq 0, k = 2, \ldots, n-1 \).
with auxiliary polynomials $G_k(x)$, and the coefficients $P_k, k = 0, \ldots, n$ are as defined in (3.8).

See the appendix, page 25, for the proof.

The formulas of the previous two theorems generalize the classical formulas for monomials, real-orthogonal polynomials, and Szegő polynomials (demonstrated below). We emphasize at this point that these formulas have limitations in the general case: Theorem 5.1 requires nonzero $g_k$ for each $k$, and Theorem 5.2 requires nonzero $b_k$ for each $k$. The next theorem is more general, and does not have any such limitations.

**Theorem 5.3 ([EGO05]-type recurrence relations).** Let $R = \{r_0(x), \ldots, r_{n-1}(x), P(x)\}$ be a system of $H$-(1,1)-q/s polynomials corresponding to an irreducible Hessenberg-(1,1)-quasiseparable matrix of size $n \times n$ with generators $\{p_k, q_k, d_k, g_k, b_k, h_k\}$ as in Definition 4.3, with the convention that $q_n = 0, b_n = 0$. Then the system of polynomials $\hat{R}$ associated with $R$ satisfy the recurrence relations below.

**Limitation: none.**

\[
\begin{bmatrix}
G_0(x) \\
\tilde{r}_0(x)
\end{bmatrix} = 
\begin{bmatrix}
-g_1 P_n \\
P_n
\end{bmatrix}, 
\quad (5.5)
\]

\[
\begin{bmatrix}
G_k(x) \\
\tilde{r}_k(x)
\end{bmatrix} = 
\begin{bmatrix}
\nu_k \\
\tilde{h}_k/b_k
\end{bmatrix} 
\begin{bmatrix}
-g_{k+1} \\
1
\end{bmatrix} 
\begin{bmatrix}
G_{k-1}(x) \\
\tilde{r}_{k-1}(x) + P_{n-k}
\end{bmatrix}, 
\quad k = 1, \ldots, n-1 
\quad (5.6)
\]

with auxiliary polynomials $G_k(x)$, and the coefficients $P_k, k = 0, \ldots, n$ are as defined in (3.8).

The proof is given in the appendix, page 26.

The recursions of this last theorem are the most applicable and will be used below to formulate a characterization of the class of $H$-(1,1)-q/s polynomials.

### 6. Computing the coefficients of the master polynomial (to be used in step 2 of Algorithm 3.2)

Note that in order to use the recurrence relations of the previous section it is necessary to decompose the master polynomial $P(x)$ into the $R$ basis; that is, the coefficients $P_k$ as in (3.8) must be computed. To this end, an efficient method of calculating these coefficients follows.

It is easily seen that the last polynomial $r_n(x)$ in the system $R$ does not affect the resulting confederate matrix $C_R(P)$. Thus, if $\hat{R} = \{r_0(x), \ldots, r_{n-1}(x), x r_{n-1}(x)\}$, we have $C_{\hat{R}}(P) = C_R(P)$. Decomposing the polynomial $P(x)$ into the $\hat{R}$ basis can be done recursively by setting $r_n^{(0)}(x) = 1$ and then for $k = 0, \ldots, n-1$ updating $r_n^{(k+1)}(x) = (x - x_{k+1}) \cdot r_n^{(k)}(x)$.

**Lemma 6.1.** Let $R = \{r_0(x), \ldots, r_n(x)\}$ be given by (3.1), and $f(x) = \sum_{i=1}^k a_i \cdot r_i(x)$, where $k < n - 1$. Then the coefficients of $x \cdot f(x) = \sum_{i=1}^{k+1} b_i \cdot r_i(x)$ can be computed by

\[
\begin{bmatrix}
b_0 \\
\vdots \\
b_k \\
b_{k+1} \\
0
\end{bmatrix} = 
\begin{bmatrix}
\frac{C_R(r_n)}{\alpha_n} \\
0 \\
\vdots \\
0
\end{bmatrix} 
\begin{bmatrix}
a_0 \\
an_k \\
0 \\
0 \\
\vdots \\
0
\end{bmatrix} 
\quad (6.1)
\]
Proof. It can be easily checked that
\[
x \cdot \begin{bmatrix} r_0(x) & r_1(x) & \cdots & r_n(x) \
    r_0(x) & r_1(x) & \cdots & r_n(x) \end{bmatrix} - \begin{bmatrix} C_R(r_n) \\ 0 & \cdots & 0 & \frac{1}{a_n} \end{bmatrix} r_n(x) = \begin{bmatrix} 0 \\ \cdots \\ 0 \end{bmatrix}.
\]
Multiplying the latter equation by the column of the coefficients we obtain (6.1).

This lemma suggests the following algorithm for computing coefficients \( \{ P_0, P_1, \ldots, P_{n-1}, P_n \} \) in (3.8) of the master polynomial.

\[\text{Algorithm 6.2. (Coefficients of the master polynomial in the R basis)}\]

\[\text{Cost: } O(n \times m(n)), \text{ where } m(n) \text{ is the cost of multiplication of an } n \times n \text{ quasiseparable matrix by a vector.}\]

\[\text{Input: A quasiseparable confederate matrix } C_R(r_n) \text{ and } n \text{ nodes } x = (x_1, x_2, \ldots, x_n).\]

1. Set \( \begin{bmatrix} P_0^{(0)} & \cdots & P_{n-1}^{(0)} & P_n^{(0)} \end{bmatrix} = \begin{bmatrix} 1 & 0 & \cdots & 0 \end{bmatrix} \)
2. For \( k = 1 : n, \)
   \[
   \begin{bmatrix} P_0^{(k)} \\ \vdots \\ P_{n-1}^{(k)} \\ P_n^{(k)} \end{bmatrix} = \left( \begin{bmatrix} C_R(x \cdot r_{n-1}(x)) \\ 0 & \cdots & 0 & 1 \\ 0 \end{bmatrix} - x_k \cdot I \right) \begin{bmatrix} P_0^{(k-1)} \\ \vdots \\ P_{n-1}^{(k-1)} \\ P_n^{(k-1)} \end{bmatrix}
   \]
   where \( R = \{ r_0(x), \ldots, r_{n-1}(x), x r_{n-1}(x) \}. \)
3. Take \( \begin{bmatrix} P_0 & \cdots & P_{n-1} & P_n \end{bmatrix} = \begin{bmatrix} P_0^{(n)} & \cdots & P_{n-1}^{(n)} & P_n^{(n)} \end{bmatrix} \)

\[\text{Output: Coefficients } \{ P_0, P_1, \ldots, P_{n-1}, P_n \} \text{ such that (3.8) is satisfied.}\]

It is clear that the computational burden in implementing this algorithm is in multiplication of the matrix \( C_R(r_n) \) by the vector of coefficients. The cost of each such step is \( O(m(n)) \), where \( m(n) \) is the cost of multiplication of an \( n \times n \) quasiseparable matrix by a vector, thus the cost of computing the \( n \) coefficients is \( O(n \times m(n)) \). Using a fast \( O(n) \) algorithm for multiplication of a quasiseparable matrix by a vector from [EG992], the cost of this algorithm is \( O(n^2) \).

7. The overall Traub-like algorithm

7.1. H-(1, 1)-q/s polynomials

In this section we specify in detail the process of computing the inverse of a Hessenberg-(1, 1)-quasiseparable-Vandermonde matrix via the Traub-like algorithm.

The algorithm takes as input the generators of the Hessenberg, (1, 1)-quasiseparable confederate matrix corresponding to the system of polynomials \( R \). In the case where the recurrence relations of the form (1.2) are known, the following algorithm can be used to compute these generators.

\[\text{Algorithm 7.1. (Preprocessing step)}\]

\[\text{Input: The set } \{ \alpha_k, \delta_k, \beta_k, \gamma_k \} \text{ such that a polynomial system } R \text{ satisfies (1.2).}\]

1. Compute the generators \( d_k \) via
   \[
d_1 = \frac{\delta_1}{\alpha_1}, \quad d_k = \frac{\delta_k}{\alpha_k} + \frac{\beta_k}{\alpha_{k-1} \alpha_k}, \quad k = 2, \ldots, n
   \]
2. Compute the generators \( p_k, q_k, g_k, b_k, h_k \) via
   \[
p_{k+1}q_k = \frac{1}{\alpha_k}, \quad g_k = \frac{d_k \beta_{k+1} + \gamma_{k+1}}{\alpha_{k+1}}, \quad k = 1, \ldots, n - 1
   \]
   \[
b_k = \frac{\beta_{k+1}}{\alpha_{k+1}}, \quad k = 2, \ldots, n - 1, \quad h_k = 1, \quad k = 2, \ldots, n
   \]

\[\text{Output: Generators } \{ p_k, q_k, d_k, g_k, b_k, h_k \} \text{ of a quasiseparable confederate matrix corresponding to a system of polynomials } R.\]
The next algorithm applies to any set of generators, and thus those arising from the recurrence relations (1.2) via the previous algorithm form a subset of all possible inputs. In this algorithm we will make use of MATLAB notations; for instance \( V_R(i : j, k : l) \) will refer to the block of \( V_R(x) \) consisting of rows \( i \) through \( j \) and columns \( k \) through \( l \).

**Algorithm 7.2.** [Traub-like inversion algorithm]

**Input:** Generators \( \{ p_k, q_k, d_k, g_k, b_k, h_k \} \) of a quasiseparable confederate matrix corresponding to a system of polynomials \( R \) and \( n \) nodes \( x = (x_1, x_2, \ldots, x_n) \).

1. **Compute the entries of diag(\( c_1, \ldots, c_n \)) via (2.2):**
   \[ c_i = \prod_{k \neq i} (x_k - x_i)^{-1}. \]

2. **Compute the coefficients \( \{ P_0, \ldots, P_n \} \) of the master polynomial \( P(x) \) as in (3.8) via Algorithm 6.2.**

3. Evaluate the \( n \) polynomials of \( \hat{R} \) with specified via (3.4) at the \( n \) nodes \( x_k \) to form \( V_R(x) \). Theorems 5.1-5.3 each provide an algorithm for this, choose ONE of the following steps:

   - **Theorem 5.1 - Three-term recurrence relations.** (Limitation: \( g_k \neq 0 \)).
     
     \[ V_R(k; 1) = P_n \begin{bmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{bmatrix}, \quad V_R(k; 2) = \frac{1}{p_{2q1}} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}, \quad V_R(k; 3) = \frac{1}{p_{2q1}} \begin{bmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{bmatrix}. \]

   (b) For \( k = 2 : n - 1 \), compute \( \hat{a}_k, \hat{d}_k, \hat{b}_k, \hat{c}_k \) via (5.2)-(5.3), and \( \hat{z}_k \) via

   \[ \hat{z}_k = \frac{1}{p_{k+1}q_k} \left( P_{n-k} - \frac{\hat{b}_k \hat{b}_{k-1}}{\hat{h}_{k-1}} P_{n-k+1} \right), \]

   and

   \[ V_R(k; k + 1) = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} - \hat{d}_k \hat{b}_k \begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{pmatrix} \]

   \[ V_R(k; k + 1) = \begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{pmatrix} \]

   Note: The product of two column vectors is understood to be componentwise.

   - **Theorem 5.2 - Szegő-like recurrence relations.** (Limitation: \( b_k \neq 0 \)).
     
     (a) \( V_R(k; 1) = P_n \begin{bmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{bmatrix} \)

     (b) For \( k = 1 : n - 1 \), compute \( v_k \) via (5.4),

     \[ u_k(x) = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} + \left( \frac{\hat{g}_k \hat{h}_k}{b_k} - \hat{d}_k \right) \begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{pmatrix}, \]

     \[ V_R(k; k + 1) = \frac{1}{p_{k+1}q_k} \begin{pmatrix} \hat{h}_k \hat{b}_k \end{pmatrix} G_R(k; k) + u_k(x) V_R(k; k) + P_{n-k} \begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{pmatrix} \]

     and

     \[ G_R(k+1) = \frac{1}{p_{k+1}q_k} \left( v_k G_R(k; k) - \hat{g}_{k+1} u_k(x) V_R(k; k) - \hat{g}_{k+1} P_{n-k} \right) \begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{pmatrix} \]

     Note: The product of two column vectors is understood to be componentwise.
**Theorem 5.3** - [EGO05]-like recurrence relations. *(Limitation: NONE.)*

(a) Set $V_R(;1) = P_n \begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix}$, $F_R(;1) = \begin{bmatrix} 0 \\ \vdots \\ 0 \end{bmatrix}$.

(b) For $k = 1 : n - 1$, compute

$$V_R(;k+1) = \frac{1}{\hat{p}_{k+1}q_k} \left( \hat{p}_k \hat{h}_k F_R(;k) + \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix} - \hat{d}_k \begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix} \right) V_R(;k) + P_{n-k} \begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix}$$

and

$$F_R(;k+1) = \frac{1}{\hat{p}_{k+1}q_k} \left( \hat{q}_k \hat{b}_k F_R(;k) - \hat{q}_k \hat{g}_k V_R(;k) \right)$$

*Note: The product of two column vectors is understood to be componentwise.*

4. Compute the inverse $V_R(x)^{-1}$ via (2.1):

$$V_R(x)^{-1} = I \cdot V_R^T(x) \cdot \text{diag}(c_1, \ldots, c_n)$$

**Output:** Entries of $V_R(x)^{-1}$, the inverse of the polynomial-Vandermonde matrix.

In what follows we show how this algorithm generalizes the previous work in the important special cases of monomials, real orthogonal polynomials, and Szegő polynomials. The reductions in all three special cases are summarized in Table 5.

*Table 5.* Reduction of derived recurrence relations in special cases.

### 7.2. Monomials. The classical Traub algorithm.

As shown in the previous section, the well known companion matrix (3.9) results when the polynomial system $R$ is simply a system of monomials. By choosing the generators $p_k = 1, q_k = 1, d_k = 0, g_k = 1, b_k = 1$, and $h_k = 0$, the matrix (4.6) reduces to (3.9), and also (4.7) reduces to the confederate matrix for the Horner polynomials (3.10). In this special case, the perturbed three-term recurrence relations of Theorem 5.1 become

$$\tilde{r}_0(x) = P_n, \quad \tilde{r}_k(x) = x\tilde{r}_{k-1}(x) + P_{n-k}, \quad \text{for } k = 1, \ldots, n$$

coinciding with the known recurrence relations for the Horner polynomials, used in the evaluation of the polynomial

$$P(x) = P_0 + P_1 x + \cdots + P_{n-1} x^{n-1} + P_n x^n.$$  \hspace{1cm} (7.2)

In fact, after eliminating the auxiliary polynomials present in Theorems 5.2 and 5.3, these recurrence relations also reduce to (7.1). Thus all of the presented recurrence relations generalize those used in the classical Traub algorithm.
7.3. Real orthogonal polynomials. The Calvetti-Reichel algorithm.

Consider the almost tridiagonal confederate matrix

\[
C_R(P) = \begin{bmatrix}
  d_1 & h_2 & 0 & \cdots & 0 & -P_0/P_n \\
  q_1 & d_2 & h_3 & \ddots & \vdots & -P_1/P_n \\
  0 & q_2 & d_3 & h_4 & 0 & \vdots \\
  \vdots & \ddots & \ddots & \ddots & \ddots & -P_{n-3}/P_n \\
  0 & \cdots & 0 & q_{n-1} & d_n & h_{n-1}/P_n
\end{bmatrix}.
\] (7.3)

The corresponding system of polynomials \( R \) satisfy three-term recurrence relations; for instance, the highlighted column implies

\[
r_3(x) = \frac{1}{q_3}(x - d_3)r_2(x) - \frac{h_3}{q_3}r_1(x)
\] (7.4)

by the definition of the confederate matrix. Thus, confederate matrices of this form correspond to systems of polynomials satisfying three-term recurrence relations, or systems of polynomials orthogonal on a real interval, and the polynomial \( P(x) \). Such confederate matrices can be seen as special cases of our general class by choosing the generators \( p_k = 1, b_k = 0 \), and \( g_k = 1 \), and in this case the matrix (4.6) reduces to (7.3).

To invert the corresponding polynomial-Vandermonde matrix by our algorithm, we first find the confederate matrix \( C_R(P) \) of the polynomial system \( \tilde{R} \) associated with \( R \). That is, we must evaluate the polynomials corresponding to the confederate matrix

\[
C_R(P) = \begin{bmatrix}
  d_n - P_{n-1}/P_n & h_n - P_{n-2}/P_n & \cdots & -P_1/P_n & -P_0/P_n \\
  q_{n-1} & d_{n-1} & \ddots & \vdots & \vdots \\
  0 & q_{n-2} & d_{n-2} & h_{n-2} & 0 \\
  \vdots & \ddots & \ddots & \ddots & \ddots \\
  0 & \cdots & 0 & q_1 & d_1
\end{bmatrix}.
\] (7.5)

Note that the highlighted column corresponds to the full recurrence relation

\[
\tilde{r}_3(x) = \frac{1}{q_{n-3}}(x - d_{n-2})\tilde{r}_2(x) - \frac{h_{n-1}}{q_{n-3}}\tilde{r}_1(x) + \frac{1}{q_{n-3}}\frac{P_{n-3}}{P_n}\tilde{r}_0(x)
\] (7.6)

In this case the perturbed three-term recurrence relations from Theorem 5.1 as well as the two-term recurrence relations from Theorem 5.3 both become

\[
\tilde{r}_k(x) = \frac{1}{q_{n-k}}(x - d_{n-k})\tilde{r}_{k-1}(x) - \frac{h_{n-k+1}}{q_{n-k}}h_{n-k+1}\tilde{r}_{k-2}(x) + \frac{1}{q_{n-k}}P_{n-k}
\] (7.7)

which coincides with the Clenshaw rule for evaluating

\[
P(x) = P_0r_0(x) + P_1r_1(x) + \cdots + P_{n-1}r_{n-1}(x) + P_n r_n(x).
\] (7.8)

Thus our formula generalizes both the Clenshaw rule and the algorithms designed for inversion of three-term-Vandermonde matrices in [CR93] and [GO94].

Notice that the Szegő-like two-term recurrence relations of Theorem 5.2 are inapplicable as \( b_k = 0 \) is a necessary choice of generators.
7.4. Szegő polynomials. The \([O98]\) algorithm.

Next consider the important special case of the almost unitary Hessenberg matrix

\[
C_R(P) = \begin{bmatrix}
-\rho_1 \rho_0 & \cdots & -\rho_{n-1} \mu_n - 2 & \cdots & -\rho_1 \rho_0 & -\rho_n \mu_{n-1} \cdots & -\rho_1 \rho_0 - P_0 / P_n \\
\mu_1 & \cdots & -\rho_{n-1} \mu_n - 2 & \cdots & -\rho_1 \rho_0 & -\rho_n \mu_{n-1} \cdots & -\rho_1 \rho_0 - P_1 / P_n \\
0 & \cdots & & \cdots & & & \\
\vdots & & & \cdots & & & \\
0 & \cdots & & & & -\rho_{n-1} \rho_{n-2} \mu_{n-1} & -\rho_n \rho_{n-1} - P_n / P_n \\
0 & \cdots & & & & -\rho_{n-1} \rho_{n-2} \mu_{n-1} & -\rho_n \rho_{n-1} - P_n / P_n
\end{bmatrix}
\tag{7.9}
\]

that corresponds to the Szegő polynomials (represented by the reflection coefficients \(\rho_k\) and complimentary parameters \(\mu_k\)) as in Section 1, and polynomial \(P(x)\). The Szegő polynomials are known to satisfy the two-term recurrence relations

\[
\begin{bmatrix}
\phi_0(x) \\
\phi_0^n(x)
\end{bmatrix} = \frac{1}{\mu_0} \begin{bmatrix} 1 & 1 \end{bmatrix},
\begin{bmatrix}
\phi_k(x) \\
\phi_k^n(x)
\end{bmatrix} = \frac{1}{\mu_k} \begin{bmatrix} 1 & -\rho_k \\
-x \phi_k^{-1}(x)
\end{bmatrix},
\tag{7.10}
\]

as well as the three-term recurrence relations

\[
\phi_0^#(x) = 1, \quad \phi_1^#(x) = \frac{1}{\mu_1} \cdot x \phi_0^#(x) - \frac{\rho_1}{\mu_1} \phi_0^#(x),
\]

\[
\phi_k^#(x) = \begin{bmatrix} 1 & \rho_k & \mu_k \end{bmatrix} \phi_{k-1}^#(x) \begin{bmatrix} \rho_k^{-1} & \mu_k \end{bmatrix} \phi_{k-2}^#(x) - \rho_k \phi_{k-1}^#(x) \begin{bmatrix} \rho_k^{-1} & \mu_k \end{bmatrix} \phi_{k-2}^#(x),
\tag{7.11}
\]

(see \([G58], [G48]\)). As above, the polynomials associated with the system of Szegő polynomials are determined by the confederate matrix

\[
C_R(P) = \begin{bmatrix}
-\rho_n \rho_{n-1} - P_{n-1} / P_n & -\rho_n \mu_{n-1} \rho_{n-2} - P_{n-2} / P_n & \cdots & -\rho_n \mu_{n-1} \cdots \mu_1 \rho_0 - P_0 / P_n \\
\mu_{n-1} & -\rho_n \mu_{n-1} \rho_{n-2} & \cdots & -\rho_n \mu_{n-1} \cdots \mu_1 \rho_0 \\
0 & \cdots & \cdots & \\
\vdots & \cdots & \cdots & \\
0 & \cdots & & \mu_1
\end{bmatrix}.
\tag{7.12}
\]

For this special case, let \(p_k = 1\), \(q_k = \mu_k\), \(d_k = -\rho_k \rho_{k-1}\), \(g_k = \rho_{k-1} \mu_k\), \(b_k = \mu_k\), \(h_k = -\rho_k\) (alternatively \(g_k = \rho_{k-1}^{-1}\), \(b_k = \mu_{k-1}\), and \(h_k = -\mu_{k-1} \rho_k\)). This choice of generators reduces (4.6) to the matrix (7.9) as well as (4.7) to (7.12), and in this case the perturbed two-term recurrence relations of Theorem 5.2 become

\[
\begin{bmatrix}
\hat{\phi}_0(x) \\
\hat{\phi}_0^n(x)
\end{bmatrix} = \frac{1}{\mu_n} \begin{bmatrix} -\rho_n \\
1
\end{bmatrix},
\begin{bmatrix}
\hat{\phi}_k(x) \\
\hat{\phi}_k^n(x)
\end{bmatrix} = \frac{1}{\mu_{n-k}} \begin{bmatrix} 1 & -\rho_{n-k} \\
-x \hat{\phi}_{k-1}^{-1}(x)
\end{bmatrix} \begin{bmatrix} \rho_{n-k}^{-1} & \mu_{n-k} \end{bmatrix} \hat{\phi}_{k-2}^#(x) + P_{n-k},
\tag{7.13}
\]

coinciding with those recurrence relations derived in \([O98]\). The recurrence relations from Theorem 5.3 reduce to new two-term recurrence relations; that is, relations that do not generalize those derived in \([O98]\). They become

\[
\begin{bmatrix}
\hat{F}_k(x) \\
\hat{F}_k^n(x)
\end{bmatrix} = \frac{1}{\mu_{n-k}} \begin{bmatrix} \mu_{n-k} \mu_{n-k+1} & -\mu_{n-k} \rho_{n-k} \\
-\mu_{n-k+1} \rho_{n-k} & x + \mu_{n-k} \rho_{n-k+1}
\end{bmatrix} \begin{bmatrix} \hat{F}_{k-1}(x) \\
\hat{F}_{k-1}^#(x)
\end{bmatrix} + \begin{bmatrix} 0 \\
P_{n-k}
\end{bmatrix},
\tag{7.14}
\]

Also, the perturbed three-term recurrence relations of Theorem 5.1 reduce to

\[
\hat{\phi}_0(x) = \frac{1}{\mu_n}, \quad \hat{\phi}_1(x) = \left\{ \frac{1}{\mu_{n-1}} \cdot x \hat{\phi}_0(x) - \frac{\rho_{n-1} \rho_n}{\mu_{n-1}} \hat{\phi}_0(x) \right\} + \frac{P_{n-1}}{\mu_{n-1}}.
\]

\[
\hat{\phi}_k(x) = \begin{bmatrix} 1 & \rho_{n-k} & \mu_{n-k} \end{bmatrix} \hat{\phi}_{k-1}(x) \begin{bmatrix} \rho_{n-k}^{-1} & \mu_{n-k} \end{bmatrix} \hat{\phi}_{k-2}(x) + \frac{P_{n-k} - P_{n-k+1} \mu_{n-k+1} \rho_{n-k+1}}{\mu_{n-k}}.
\tag{7.15}
\]

in this case, also coinciding with the perturbed three-term recurrence relations in \([O98]\). Thus both of these theorems generalize the recurrence relations derived in \([O98]\) as well.
8. Full characterizations of H-(1, 1)-q/s polynomials via recurrence relations

One reason that Algorithm 7.2 is fast is that it converts the generators of the quasiseparable confederate matrix into coefficients of recurrence relations for the associated system of polynomials \( \tilde{R} \) involved in the inversion formula (2.1) for \( V_R(x)^{-1} \). In fact, we have presented three such conversion methods, summarized along with their cases of applicability in Table 6.

<table>

<td>Theorem 5.3</td>
<td>none</td>
</tr>
</tbody>
</table>

Table 6. Conversion formulas for the system of associated polynomials \( \tilde{R} \).

With these conversions, the derivation of the Traub-like algorithm is complete, however, there are still two questions left to answer. Both questions are related not to the associated polynomials \( R \) (for which the results are listed in Table 6) but are related to the original polynomial system \( R \) involved in the original polynomial-Vandermonde matrix \( V_R(x) \).

The first question is as follows. The input of Algorithm 7.2 is the set of generators of a Hessenberg-(1, 1)-quasiseparable matrix \( C_R^{(r_n)} \), and the algorithm applies to the class of H-(1, 1)-q/s polynomials. Hence one may want to give a complete characterization of this class in terms of various recurrence relations satisfied.

Secondly, in many applications polynomials are given in terms of their recurrence relations, and in order to run Algorithm 7.2 one needs to include a preprocessing step for this conversion, such as that specified in Theorem 4.7 and Algorithm 7.1.

In this section we answer the above two questions and derive the shaded results listed in Table 7. Results not shaded have previously been stated.

</tbody>
</table>

Table 7. Conversion formulas for the system of polynomials \( R \).

8.1. Three-term recurrence relations

The result in Theorem 4.7 tells us that if polynomials \( r_k \) satisfy the recurrence relations (1.2) then the corresponding confederate matrix \( A \) has a nice structure. Precisely, \( A \) is a (1, 1)-quasiseparable matrix given by the generators (4.3)-(4.5). Notice that it is guaranteed from (4.5) that \( h_k = 1, k = 2, \ldots, n \). The next statement shows that, provided \( h_k \neq 0 \), the converse is also true.

**Corollary 8.1 (Quasiseparable generators ⇒ recurrence relations coefficients).** Let \( C_R^{(r_n)} \) be an irreducible Hessenberg-(1, 1)-quasiseparable matrix specified by the generators \( \{p_k, q_k, d_k, g_k, b_k, h_k\} \) with \( h_k \neq 0 \) for \( k = 2, \ldots, n \). Then the polynomial system \( R \) with confederate matrix \( C_R^{(r_n)} \) satisfies (1.2) with

\[
\alpha_k = \frac{1}{p_k+1} g_k, \quad \delta_k = \frac{1}{p_k+1} q_k \left( d_k - \frac{p_k q_{k-1} b_{k-1} h_k}{h_{k-1}} \right) \quad (8.1)
\]

\[
\beta_k = \frac{1}{p_k+1} \frac{h_k b_{k-1}}{h_{k-1}}, \quad \gamma_k = \frac{1}{p_k+1} q_k \frac{h_k}{h_{k-1}} \left( h_{k-1} g_{k-1} - d_{k-1} b_{k-1} \right) \quad (8.2)
\]

This relation is in fact a corollary of Theorem 5.1. Indeed, the corresponding matrix of the generators presented in Theorem 5.1 is of the form (4.7), and that of Corollary 8.1 is of the form (4.6). Hence we can see that the recurrence relations (8.1), (8.2) are specifications of (5.2), (5.3).

Theorem 4.7 and Corollary 8.1 give not only a method of computing generators from parameters of the recurrence relations and vice versa, but they also together give a characterization of polynomials satisfying (1.2) in terms of their quasiseparable matrices, stated as the following corollary.
Corollary 8.2. Let $R = \{r_0(x), \ldots, r_n(x)\}$ be a polynomial system s.t. $\deg(r_k) = k$ and denote by $C_R(r_n)$ the irreducible upper Hessenberg confederate matrix of $r_n(x)$ with respect to $R$. Then the system $R$ satisfies the recurrence relations (1.2) if and only if $C_R(r_n)$ is $(1,1)$-quasiseparable with $h_k \neq 0$ for $k = 2, \ldots, n$.

Although the condition $h_k \neq 0$ may look unnecessary when one starts with the matrices, when beginning with the polynomials satisfying (1.2) and converting to matrices, the condition $h_k = 1$ is automatically satisfied as shown in (4.5).

8.2. Szegő-type recurrence relations

Theorem 8.3 (Recurrence relation coefficients $\Rightarrow$ quasiseparable generators). Let $R = \{r_0(x), \ldots, r_n(x)\}$ be a system of polynomials s.t. $\deg(r_k) = k$ and denote by $C_R(r_n)$ the confederate matrix of $r_n(x)$ with respect to $R$. Suppose $R$ satisfies the recurrence relations

$$
\begin{bmatrix}
G_k(x) \\
r_k(x)
\end{bmatrix} =
\begin{bmatrix}
\alpha_k & \beta_k \\
\gamma_k & 1
\end{bmatrix}
\begin{bmatrix}
G_{k-1}(x) \\
(\delta_k x + \theta_k) r_{k-1}(x)
\end{bmatrix}
$$

Then $C_R(r_n)$ is an irreducible Hessenberg-(1,1)-quasiseparable matrix with generators

$$
d_1 = -\theta_1 - \gamma_1,
\quad d_k = -\frac{\theta_k + \gamma_k \beta_{k-1}}{\delta_k}, \quad k = 2, \ldots, n
\quad p_k = 1, \quad k = 2, \ldots, n
\quad g_k = \frac{1}{\delta_k}, \quad k = 1, \ldots, n - 1
\quad b_k = \alpha_{k-1} - \beta_{k-1} \gamma_{k-1}, \quad k = 2, \ldots, n - 1
\quad h_k = -\frac{\gamma_k}{\delta_k} (\alpha_{k-1} - \beta_{k-1} \gamma_{k-1}), \quad k = 2, \ldots, n
$$

For the proof, see the appendix.

Corollary 8.4 (Quasiseparable generators $\Rightarrow$ recurrence relations coefficients). Let $C_R(r_n)$ be an irreducible Hessenberg-(1,1)-quasiseparable matrix specified by the generators $\{p_k, q_k, d_k, g_k, b_k, h_k\}$ with $b_k \neq 0$ for $k = 2, \ldots, n - 1$. Then the polynomial system $R$ with confederate matrix $C_R(r_n)$ satisfies

$$
\begin{bmatrix}
G_0(x) \\
r_0(x)
\end{bmatrix} =
\begin{bmatrix}
-g_1 \\
1
\end{bmatrix},
$$

$$
\begin{bmatrix}
G_k(x) \\
r_k(x)
\end{bmatrix} =
\frac{1}{p_{k+1} q_k}
\begin{bmatrix}
v_k \\
h_k / b_k
\end{bmatrix}
\begin{bmatrix}
-g_{k+1} \\
1
\end{bmatrix}
\begin{bmatrix}
G_{k-1}(x) \\
(\alpha_k x + \beta_k) r_{k-1}(x)
\end{bmatrix}
$$

with

$$
u_k(x) = (x - d_k) + \frac{g_k h_k}{b_k}, \quad
v_k = p_{k+1} b_{k+1} q_k - \frac{g_{k+1} h_k}{b_k}.
$$

As in the case of the three-term recurrence relations, Theorem 8.3 and Corollary 8.4 together give a characterization of polynomials satisfying two-term recurrence relations of the form (8.5) in terms of their quasiseparable matrices, stated as the following corollary.

Corollary 8.5. Let $R = \{r_0(x), \ldots, r_n(x)\}$ be a polynomial system s.t. $\deg(r_k) = k$ and denote by $C_R(r_n)$ the irreducible upper Hessenberg confederate matrix of $r_n(x)$ with respect to $R$. Then the system $R$ satisfies the recurrence relations (8.5) if and only if $C_R(r_n)$ is $(1,1)$-quasiseparable with $b_k \neq 0$ for $k = 2, \ldots, n - 1$. 
8.3. [EGO05]-type recurrence relations

Theorem 8.6 (Recurrence relation coefficients ⇒ quasiseparable generators). Let \( R = \{r_0(x), \ldots, r_n(x)\} \) be a system of polynomials s.t. \( \deg(r_k) = k \) and denote by \( C_R(r_n) \) the confederate matrix of \( r_n(x) \) with respect to \( R \). Suppose \( R \) satisfies the recurrence relations

\[
\begin{bmatrix}
G_k(x) \\
r_k(x)
\end{bmatrix} = \begin{bmatrix}
\alpha_k & \beta_k \\
\gamma_k & \delta_k x + \theta_k
\end{bmatrix} \begin{bmatrix}
G_{k-1}(x) \\
r_{k-1}(x)
\end{bmatrix} \tag{8.7}
\]

Then \( C_R(r_n) \) is an irreducible Hessenberg-(1, 1)-quasiseparable matrix with generators

\[
d_k = -\frac{\theta_k}{\delta_k}, \quad k = 1, \ldots, n
\]
\[
p_k = 1, \quad k = 2, \ldots, n
\]
\[
q_k = \frac{1}{\delta_k}, \quad k = 1, \ldots, n - 1
\]
\[
g_k = \beta_k, \quad k = 1, \ldots, n - 1
\]
\[
b_k = \alpha_k, \quad k = 2, \ldots, n - 1
\]
\[
h_k = -\frac{\gamma_k}{\delta_k}, \quad k = 2, \ldots, n
\]

For the proof of this result, see the appendix.

Corollary 8.7 (Quasiseparable generators ⇒ recurrence relations coefficients). Let \( C_R(r_n) \) be an irreducible Hessenberg-(1, 1)-quasiseparable matrix specified by the generators \( \{p_k, q_k, d_k, g_k, b_k, h_k\} \). Then the polynomial system \( R \) with confederate matrix \( C_R(r_n) \) satisfies

\[
\begin{bmatrix}
F_k(x) \\
r_k(x)
\end{bmatrix} = \frac{1}{p_{k+1}q_k} \begin{bmatrix}
p_k p_k b_k & -q_k g_k \\
p_k h_k & x - d_k
\end{bmatrix} \begin{bmatrix}
F_{k-1}(x) \\
r_{k-1}(x)
\end{bmatrix}. \tag{8.8}
\]

There are no restrictions required for these recurrence relations to be applicable as in the recurrence relations above which generalize classical relations. As a result, these recurrence relations completely characterize H-(1, 1)-q/s polynomials:

Corollary 8.8. Let \( R = \{r_0(x), \ldots, r_n(x)\} \) be a polynomial system s.t. \( \deg(r_k) = k \) and denote by \( C_R(r_n) \) the irreducible upper Hessenberg confederate matrix of \( r_n(x) \) with respect to \( R \). Then the system \( R \) satisfies the recurrence relations (8.8) if and only if \( C_R(r_n) \) is (1, 1)-quasiseparable.

9. Numerical Experiments

The numerical properties of the Traub algorithm and its generalizations (that are the special cases of our general algorithm) were studied by different authors. It was noticed in [GO97] that a version of the Traub algorithm can yield high accuracy in certain cases if the algorithm is preceded with the Leja ordering of the nodes; that is, ordering such that

\[
|x_1| = \max_{1 \leq i \leq n} |x_i|, \quad \prod_{j=1}^{k-1} |x_k - x_j| = \max_{k \leq i \leq n} \prod_{j=1}^{k-1} |t_i - t_j|, \quad k = 2, \ldots, n - 1
\]

(see [RO91], [H90], [O03]) It was noticed in [GO97] that the same is true for Chebyshev-Vandermonde matrices.

No error analysis was done, but the conclusions of the above authors was that in many cases the Traub algorithm and its extensions can yield much better accuracy than Gaussian elimination, even for very ill-conditioned matrices.

We made our preliminary experiments with the general algorithm, and our conclusions are consistent with the experience of our colleagues. In all cases we studied the proposed algorithm yields better accuracy than Gaussian elimination, e.g., in the new special cases of Szegő-Vandermonde and Hessenberg-(1, 1)-quasiseparable-Vandermonde matrices. However, our experiments need to be done for different special cases and also the numerical properties of different recurrence relations are worth analyzing.

The algorithm has been implemented in MATLAB version 7. The results of the algorithm using standard MATLAB code, and hence double precision arithmetic, were compared with exact solutions calculated using
the MATLAB Symbolic Toolbox command `vpa()`, which allows software-implemented precision of arbitrary numbers of digits. The number of digits was set to 64, however in cases where the condition number of the coefficient matrix exceeded $10^{30}$, this was raised to 100 digits to maintain accuracy.

We compare the forward accuracy of the inverse computed by the algorithm with respect to the inverse computed in high precision, defined by

$$
e = \frac{\|V_R(x)^{-1} - \widehat{V}_R(x)^{-1}\|_2}{\|V_R(x)^{-1}\|_2}$$

where $\widehat{V}_R(x)^{-1}$ is the solution computed by each algorithm in MATLAB in double precision, and $V_R(x)^{-1}$ is the exact solution. In the tables, TraubQS denotes the proposed Traub-like algorithm, and `inv()` indicates MATLAB’s inversion command. Finally, `cond(V)` denotes the condition number of the matrix $V$ computed via the MATLAB command `cond()`.

**Experiment 1.** In this experiment, the problem was chosen by choosing the generators that define the recurrence relations of the polynomial system randomly in $(-1, 1)$, and the nodes $x_k$ were selected equidistant on $(-1, 1)$ via the formula

$$x_k = -1 + 2 \left( \frac{k}{n-1} \right), \quad k = 0, 1, \ldots, n - 1$$

We test the accuracy of the inversion algorithm for various sizes $n$ of matrices generated in this way. Some results are tabulated in Table 8, and shown graphically in Figure 1.

Table 9. Random parameters on the unit disc.
10. Conclusions

In this paper we used properties of confederate matrices to extend the classical Traub algorithm for inversion of Vandermonde matrices to the general polynomial-Vandermonde case. The relation between polynomial systems satisfying some recurrence relations and quasiseparable matrices allowed an order of magnitude computational savings in this case, resulting in an $O(n^2)$ algorithm as opposed to Gaussian elimination, which requires $O(n^3)$ operations. The connection between the various sparse recurrence relations derived for this purpose was investigated, and the result is a complete characterization of the system of polynomials studied in terms of the related quasiseparable matrix. Finally, some numerical experiments were presented that indicate that, under some circumstances, the resulting algorithm can give better performance than Gaussian elimination.

Appendix

Proof of Theorem 4.7. We prove by induction on $k$ that the choice of generators (4.3)-(4.5) results in the $n$-term recurrence relations (4.2) corresponding to an irreducible Hessenberg-(1,1)-quasiseparable matrix.

For $k = 1$, the recurrence relations (1.2) result in

$$r_1(x) = (\alpha_1 x - \delta_1) r_0(x),$$

(A.1)

and using (4.3)-(4.5) we arrive at (4.2) for $k = 1$. For $k = 2$, inserting the relation

$$x r_0(x) = \frac{1}{\alpha_1} (r_1(x) + \delta_1 r_0(x))$$

from (A.1) into

$$r_2(x) = (\alpha_2 x - \delta_2) r_1(x) - (\beta_2 x + \gamma_2) r_0(x)$$

results in

$$r_2(x) = \left( \alpha_2 x - \left( \delta_2 + \frac{\beta_2}{\alpha_1} \right) \right) r_1(x) - \left( \beta_2 \frac{\delta_1}{\alpha_1} + \gamma_2 \right) r_0(x),$$

and again using (4.3)-(4.5) this becomes

$$r_2(x) = \frac{1}{p_2 q_2} [ (x - d_2) r_1(x) - g_1 r_0(x) ]$$
which is (4.2) for \( k = 2 \).

Next suppose the choice of generators (4.3)-(4.5) results in (4.2) for some \( k - 1 \) with \( k \geq 3 \). By adding and subtracting the quantity \( \frac{d_{k-1}}{\alpha_{k-1}} r_{k-1}(x) \) to (1.2), we have

\[
r_k(x) = \alpha_k \left[ \left( x - \frac{\beta_k}{\alpha_k} \right) r_{k-1}(x) + \left( \frac{\beta_k}{\alpha_k} \right) r_{k-1}(x) - \left( \frac{\beta_k}{\alpha_k} x + \frac{\gamma_k}{\alpha_k} \right) r_{k-2}(x) \right].
\]

(A.2)

By the inductive hypothesis,

\[
\left( \frac{\beta_k}{\alpha_k} \right) r_{k-1}(x) - \left( \frac{\beta_k}{\alpha_k} x + \frac{\gamma_k}{\alpha_k} \right) r_{k-2}(x) = -\sum_{j=0}^{k-3} g_{j+1} b_{j+1,k-1} \frac{\beta_k}{\alpha_k} r_j(x),
\]

and using (4.3)-(4.5), this is furthermore equal to

\[
-g_{k-1} r_{k-2}(x) - \sum_{j=0}^{k-3} g_{j+1} b_{j+1,k-1} b_{k-1} r_j(x) = \sum_{j=0}^{k-3} g_{j+1} b_{j+1,k} \frac{\beta_k}{\alpha_k} r_j(x)
\]

(A.3)

using the identities \( b_{k-1,k-1} = 1 \) and \( b_{j+1,k-1} b_{k-1} = b_{j+1,k} \). Inserting (A.3) into (A.2) and using (4.3) once more gives (4.2) for \( k \). This completes the proof.

\[ \square \]

**Proof of Theorem 5.1.** Let \( S = \{s_0(x), s_1(x), \ldots, s_{n-1}(x)\} \) be the system of polynomials corresponding to the Hessenberg order (1,2)-quasiseparable matrix \( C_R(P) \) of the form in (4.7). Then from (3.1) and (4.7), we have for \( k = 1, 2, \ldots, n - 1 \)

\[
s_k(x) = \frac{1}{p_{k+1}q_k} \left[ \left( x - \hat{d}_k \right) s_{k-1}(x) - \hat{g}_{k-1} \hat{h}_k s_{k-2}(x) - \hat{g}_{k-2} \hat{b}_{k-1} \hat{h}_k s_{k-3}(x) \right.
\]

\[
- \cdots - \hat{g}_2 \hat{b}_1 \ldots \hat{b}_{k-1} \hat{h}_k s_1(x) - \hat{g}_1 \hat{b}_2 \cdots \hat{b}_{k-1} \hat{h}_k s_0(x) + P_{n-k} \left].
\]

(A.4)

It suffices to show that the system of polynomials \( \{\hat{r}_0(x), \hat{r}_1(x), \ldots, \hat{r}_{n-1}(x)\} \) defined by the recurrence relations in (5.1)-(5.3) coincide with those given by Theorem 5.1. From (5.6) and the relationship

\[
\left( \begin{array}{c} v_k + \frac{g_{k+1}}{\hat{b}_k} h_k/b_k \\ \hat{h}_k/b_k \\
\end{array} \right) = \left[ \begin{array}{c} \frac{1}{\hat{h}_k/b_k} \frac{g_{k+1}}{\hat{b}_k} \\ v_k \\
\end{array} \right]
\]

(A.7)
we obtain
\[
\left(v_k + \frac{\hat{g}_k + \hat{h}_k}{b_k}\right) \left[ \frac{G_{k-1}(x)}{u_k(x)\hat{r}_{k-1}(x) + P_{n-k}} \right] = \frac{1}{\hat{h}_k} \hat{r}_{k-1}(x) + \hat{P}_{k+1} \hat{G}_k(x) \frac{G_k(x)}{\hat{r}_k(x)} \right]
\]
(A.8)

Thus, we have the following expression for \( u_k(x)\hat{r}_{k-1}(x) + P_{n-k} \),
\[
\left(v_k + \frac{\hat{g}_k + \hat{h}_k}{b_k}\right) (u_k(x)\hat{r}_{k-1}(x) + P_{n-k}) = \hat{P}_{k+1} \hat{G}_k(x) + v_k\hat{r}_k(x)
\]
(A.9)

Using (5.6) for \( k+1 \), we have that
\[
\hat{P}_{k+2} \hat{G}_k(x) + u_k\hat{r}_k(x) + P_{n-k-1}
\]
which gives that \( G_k(x) \) is given by
\[
G_k(x) = \left( \frac{\hat{b}_k}{\hat{h}_k} \right) (\hat{P}_{k+2} \hat{G}_k(x) + u_k\hat{r}_k(x) - P_{n-k-1})
\]
(A.10)

Inserting (A.11) into (A.9) and shifting from \( k+1 \) to \( k \), we arrive at (5.1) as desired. Using the assumptions and \( g_j \neq 0 \) for each \( k \), Theorem 5.1 implies the result.

For the case of a polynomial system \( R \) where \( g_j = 0 \) for some \( j \), note that the coefficients of the polynomials generated by the two-term recurrence relations (8.5) depend continuously on the entries of the \( 2 \times 2 \) transfer matrix. Let \( \{\epsilon_k\} \) be a sequence tending to zero with \( \epsilon_k \neq 0 \) for each \( k \), and consider a sequence of systems of polynomials \( R_k \) with \( g_j = \epsilon_k \) for each \( j \) such that \( g_j = 0 \) in the original polynomial system \( R \), and all other generators the same as in \( R \). Then the result of the theorem holds for the system \( R_k \) for every \( k \) by above, and \( R_k \to R \), so by continuity, the result must hold for \( R \) as well. This completes the proof.

Proof of Theorem 5.3. The recurrence relations (5.8) define a system of polynomials which satisfy the \( n \)-term recurrence relations
\[
\hat{r}_k(x) = (a_k x - a_{k-1},k) \cdot \hat{r}_{k-1}(x) - a_{k-2,k} \cdot \hat{r}_{k-2}(x) - \ldots - a_{0,k} \cdot \hat{r}_{0}(x)
\]
(A.12)
for some coefficients \( a_k, a_{k-1,k}, \ldots, a_{0,k} \). The proof is presented by showing that these \( n \)-term recurrence relations in fact coincide exactly with (4.8), so these coefficients coincide with those of the \( n \)-term recurrence relations of the associated polynomials \( \hat{R} \); that is,
\[
\alpha_k = \frac{1}{\hat{P}_{k+1} \hat{q}_k}, \quad a_{k-1,k} = \frac{1}{\hat{P}_{k+1} \hat{q}_k} \hat{d}_k, \quad a_{0,k} = \frac{1}{\hat{P}_{k+1} \hat{q}_k} \left( \hat{g}_k \hat{b}_{k+1} \hat{h}_k - \frac{P_{n-k}}{P_n} \right)
\]
(A.13)

Using relations for \( \hat{r}_k(x) \) and \( \hat{F}_{k-1}(x) \) from (5.8), we have
\[
\hat{r}_k(x) = \frac{1}{\hat{P}_{k+1} \hat{q}_k} \left[ (x - \hat{d}_k)\hat{r}_{k-1}(x) - \hat{g}_k \hat{h}_k \hat{r}_{k-2}(x) + \hat{h}_k \hat{P}_{k+1} \hat{r}_{k-1}(x) + \frac{P_{n-k}}{P_n} \hat{r}_0(x) \right].
\]
(A.14)

Notice that again using (5.8) to eliminate \( \hat{F}_{k-2}(x) \) from the equation (A.14) will result in an expression for \( \hat{r}_k(x) \) in terms of \( \hat{r}_{k-1}(x), \hat{r}_{k-2}(x), \hat{r}_{k-3}(x), \hat{F}_{k-3}(x), \) and \( \hat{r}_0(x) \) without modifying the coefficients of \( \hat{r}_{k-1}(x), \hat{r}_{k-2}(x), \) or \( \hat{r}_0(x) \). Again applying (5.8) to eliminate \( \hat{F}_{k-3}(x) \) results in an expression in terms of \( \hat{r}_{k-1}(x), \hat{r}_{k-2}(x), \hat{r}_{k-3}(x), \hat{r}_{k-4}(x), \hat{F}_{k-4}(x), \) and \( \hat{r}_0(x) \) without modifying the coefficients of \( \hat{r}_{k-1}(x), \hat{r}_{k-2}(x), \hat{r}_{k-3}(x), \) or \( \hat{r}_0(x) \). Continuing in this way, the \( n \)-term recurrence relations of the form (A.12) are obtained without modifying the coefficients of the previous ones.

Suppose that for some \( 0 \leq j < k \) the expression for \( \hat{r}_k(x) \) is of the form
\[
\hat{r}_k(x) = \frac{1}{\hat{P}_{k+1} \hat{q}_k} \left[ (x - \hat{d}_k)\hat{r}_{k-1}(x) - \hat{g}_k \hat{h}_k \hat{r}_{k-2}(x) - \ldots - \hat{g}_{j+1} \hat{b}_{j+1,k} \hat{h}_{j,k} \hat{r}_j(x) \right] + \hat{P}_{j+1} \hat{b}_{j+1,k} \hat{h}_{j,k} \hat{F}_j(x) + \frac{P_{n-k}}{P_n} \hat{r}_0(x)
\]
(A.15)
Using (5.8) for \( \tilde{F}_j(x) \) gives the relation

\[
\tilde{F}_j(x) = \frac{1}{p_{j+1}q_j} \left( \tilde{q}_j \tilde{p}_j \tilde{b}_j \tilde{F}_{j-1}(x) - \tilde{q}_j \tilde{p}_j \tilde{F}_{j-1}(x) \right) \quad (A.16)
\]

Inserting (A.16) into (A.15) gives

\[
\hat{r}_k(x) = \frac{1}{p_{k+1}q_k} \left[ (x - \tilde{a}_k)\hat{r}_{k-1}(x) - \tilde{g}_{k-1} \hat{h}_k \hat{r}_{k-2}(x) - \cdots - \tilde{g}_{j} \tilde{b}_j \hat{h}_k \hat{r}_{j-1}(x) \right. \\
\left. + \tilde{p}_j \tilde{b}_j^{\times} \hat{h}_k \tilde{F}_{j-1}(x) + \frac{P_{n-k}}{P_n} \hat{r}_0(x) \right].
\]

(A.17)

Therefore since (A.14) is the case of (A.15) for \( j = k - 2 \), (A.15) is true for each \( j = k - 2, k - 3, \ldots, 0 \), and for \( j = 0 \), using the fact that \( \hat{F}_0 = 0 \) we have

\[
\hat{r}_k(x) = \frac{1}{p_{k+1}q_k} \left[ (x - \tilde{a}_k)\hat{r}_{k-1}(x) - \tilde{g}_{k-1} \hat{h}_k \hat{r}_{k-2}(x) - \cdots - \tilde{g}_1 \tilde{b}_1 \hat{h}_k \hat{r}_0(x) + \frac{P_{n-k}}{P_n} \hat{r}_0(x) \right] \quad (A.18)
\]

Since these coefficients coincide with those in (A.13) that are satisfied by the associated polynomials, the polynomials given by (5.8) must coincide with the associated polynomials. This proves the theorem.

**Proof of Theorem 8.3.** The specified generators in conjunction with the general \( n \)-term recurrence relations (4.2) give

\[
r_k(x) = (\delta_k x + \theta_k + \gamma_k \beta_{k-1})r_{k-1}(x) + \gamma_k (\alpha_{k-1} - \beta_{k-1} \gamma_{k-1}) \beta_{k-2} r_{k-2}(x) \\
+ \gamma_k (\alpha_{k-1} - \beta_{k-1} \gamma_{k-1})(\alpha_{k-2} - \beta_{k-2} \gamma_{k-2}) \beta_{k-3} r_{k-3}(x) + \cdots + \\
+ \gamma_k (\alpha_{k-1} - \beta_{k-1} \gamma_{k-1})(\alpha_{k-2} - \beta_{k-2} \gamma_{k-2}) \cdots (\alpha_2 - \beta_2 \gamma_2) \beta_1 r_1(x) + \\
+ \gamma_k (\alpha_{k-1} - \beta_{k-1} \gamma_{k-1})(\alpha_{k-2} - \beta_{k-2} \gamma_{k-2}) \cdots (\alpha_2 - \beta_2 \gamma_2)(\alpha_1 - \beta_1 \gamma_1) r_0(x)
\]

(A.19)

The proof is presented by showing that the polynomial system satisfying the two-term recurrence relations also satisfies these \( n \)-term recurrence relations. By applying the given two-term recursion, we have

\[
\begin{bmatrix}
G_1(x) \\
G_2(x)
\end{bmatrix} =
\begin{bmatrix}
\beta_1 r_1(x) + \alpha_1 - \beta_1 \gamma_1 \\
\delta_1 x + \theta_1 + \gamma_1
\end{bmatrix}
\]

and

\[
\begin{bmatrix}
G_2(x) \\
G_2(x)
\end{bmatrix} =
\begin{bmatrix}
(\delta_2 \delta_2 x + \beta_2 \theta_2 + \alpha_2 \beta_1) r_1(x) + \alpha_2 (\alpha_1 - \beta_1 \gamma_1) \\
(\delta_2 x + \theta_2 + \gamma_2 \beta_1) r_1(x) + \gamma_2 (\alpha_1 - \beta_1 \gamma_1)
\end{bmatrix}
\]

(A.20)

giving the result for \( k = 1, 2 \). From (A.20), we have

\[
\delta_2 x r_1(x) = r_2(x) - (\theta_2 + \gamma_2 \beta_1) r_1(x) - \gamma_2 (\alpha_1 - \beta_1 \gamma_1)
\]

and inserting this into the expression for \( r_3(x) \) of the form

\[
r_3(x) = \gamma_3 G_3(x) + (\delta_3 x + \theta_3) r_2(x)
\]

yields (A.19) for \( k = 3 \). Continuing in this fashion, the result follows.

**Proof of Theorem 8.6.** Inserting the specified choice of generators into the general \( n \)-term recurrence relations (4.2), we arrive at

\[
r_k(x) = (\delta_k x + \theta_k) r_{k-1}(x) + \gamma_k \beta_{k-1} r_{k-2}(x) + \gamma_k \alpha_{k-1} \beta_{k-2} r_{k-3}(x) \\
+ \gamma_k \alpha_{k-1} \alpha_{k-2} \beta_{k-3} r_{k-4}(x) + \cdots + \gamma_k \alpha_{k-1} \cdots \alpha_2 \beta_1 r_0(x)
\]

(A.21)

It suffices to show that the polynomial system satisfying the two-term recurrence relations also satisfies these \( n \)-term recurrence relations. Beginning with

\[
r_k(x) = \gamma_k G_{k-1}(x) + (\delta_k x + \theta_k) r_{k-1}(x)
\]

(A.22)

and using the relation

\[
G_{k-1}(x) = \alpha_{k-1} G_{k-2}(x) + \beta_{k-1} r_{k-2}(x)
\]

(A.22) becomes

\[
r_k(x) = \gamma_k \alpha_{k-1} G_{k-2}(x) + \gamma_k \beta_{k-1} r_{k-2}(x) + (\delta_k x + \theta_k) r_{k-1}(x)
\]

and, using a similar argument as in the proof of Theorem 5.3, we continue this procedure to obtain \( n \)-term recurrence relations. It can easily be checked that this procedure yields exactly (A.21).
